Language and Literature

Abstract

The linguistic processing of poetry involves focus on the verbatim form of the line as a whole unit in working memory, with epistemic and affective consequences. The form of text can also be part of its meaning. Language is used in narrative to structure the represented world and engage us in specific ways with its fictional people. Linguistic form in literature can be different in interesting ways from ordinary language: attenuated, deviant, and with added regularities.

The Significance of Verbatim Language in Literature

When a person processes language, sounds, words, and syntactic structures are identified; we might distinguish between the verbatim form of language (the actual sounds and words, in the order in which they are pronounced), the underlying form (the complex linguistic representation which underlies the verbatim form and gives it its linguistic structure), and the gist – the meaning which can be extracted from the verbatim/underlying form. Much of the processing of the sounds or letters which form the linguistic input is devoted to extracting gist; that is, the verbatim (and underlying) form serves essentially to get to the stage of extracting a coded meaning. However, in the processing of a literary text, the verbatim form of the text takes on a particular importance, needing to be attended to and remembered. That is, the actual sounds, words, and surface textual organization are (in principle) important in the processing of the language of literature. Roman Jakobson made this point in a seminal article on literary linguistics (Jakobson, 1960); he identified various functions of language, including the poetic function (which is the dominant function in literature), and suggested that the poetic function was best performed by texts which manifested a 'focus on the message,' by which he meant a focus on the verbatim linguistic form of the text.

The study of the language of literature is thus dominated by the study of the specific verbatim form of a text, rather than by the meanings which are coded in it: the reader or hearer's attention to the verbatim form is often seen as providing different kinds of meaning or other effects than are produced in ordinary language processing. However, other aspects of linguistic form, which are not verbatim, are also potentially relevant: in some traditions, aspects of underlying (rather than surface verbatim) phonological form appear to be relevant to how meter, rhyme, and alliteration are processed; *see chapter by Hanson for further discussion*.

Linguistic Form in Literature

In some kinds of literature, particularly in verse, patterns appear in the language of the text. These patterns can be regular and predictable, in which case we say that they are imposed by rule, or they can emerge less predictably in the text. Consider, for example, the type of pattern called 'alliteration,' in which nearby words begin with the same consonant. In Old English poetry, the line is divided into two halves, with a rule that at least one word in the first half must alliterate with at most one word in the second half:

Oft Scyld Scēfing sceathena thrēatum
Monegum mægthum meodo-setla oftēah

> often Scyld the son of Scef, the enemy troops / of many nations the mead-benches took away.
>
> *Beowulf* (lines 4–5).

This is a regular pattern, a form which is imposed on the text by rule. Alliteration also appears in modern English verse, but never predictably: a line may have several alliterating words in it but there is no requirement for alliteration nor is there any regulation of alliteration of the kind we have just seen in Old English. Consider, for example, these lines by the seventeenth-century poet John Dryden in which the second line alliterates internally on 'd' but the surrounding lines do not alliterate at all.

> And therefore 'tis no wonder if we see
> They dot on dowdies and deformity;
> Ev'n what they cannot praise they will not blame
> But veil with some extenuating name:
>
> John Dryden *Concerning the Nature of Love* 1685 (lines 141–144).

Dryden's text demonstrates alliteration as an irregular pattern, which emerges in the text rather than being imposed by rule on the text.

Both of the quoted texts demonstrate another kind of form, meter, which is differently regulated in each case; meter governs the overall length of the line, and controls its rhythm. In Beowulf, each line is divided into halves, with a normative pattern where each half line has two stressed syllables, and the two stressed syllables in the first half alliterate and with the first stressed syllable in the second half; there are many variations on this basic pattern, but every line shows some variation on it. This meter is 'strong stress meter.' In Dryden's text every line has 10 syllables and even-numbered syllables tend to be stressed: this meter is 'iambic pentameter.' The Dryden text further demonstrates (regulated) rhyme: in every pair of lines, the final words rhyme. The Dryden text also

 http://dx.doi.org/10.1016/B978-0-08-097086-8.53056-6

demonstrates emergent (and irregular) parallelism, where adjacent parts of text have the same syntactic structure involving related but different words: 'they cannot praise – they will not blame.' In some literature, parallelism is strictly regulated; in English it is not. (For more detail on linguistic accounts of the regulation of linguistic form in verse *see chapter by Hanson*.)

Why do literary texts have added form? Jakobson (1960) argued that these added forms – both regular and irregular – function to draw attention to the verbatim language of the text, and hence manifest the poetic function. Richard Bauman (1975) suggests that the production of verbal art should be seen as the performance of texts which can be evaluated, and that the added forms offer criteria for evaluation; for example, the author is evaluated on how he or she meets the formal requirements for a text of a particular type.

A third possibility relates to the stylistic notion of 'markedness,' which depends on a norm which is transgressed, with consequences for interpretation. Where regular forms are stipulated, markedness can be produced by deviations from strict regularity: in many traditions, the regular forms set a norm but allow variations. Thus English iambic pentameter normatively requires 10 syllables to the line and all and only even-numbered syllables are stressed; many lines in this meter legitimately deviate somewhat from this, thus allowing markedness to emerge. (For example, in Dryden's verse, there are often fewer than five stresses in the line, even though there are always five even-numbered syllables; the stress patterns change from line to line even though the lines are always in the same meter.) Markedness can thus be produced by variation against a regular formal norm, but it can also be produced by a form emerging against a norm of its being absent; thus the alliterating pattern in Dryden's text is marked in a text which otherwise does not manifest alliteration in any regular way. The forms of verse thus allow markedness to emerge.

Markedness is a standard notion in formalist literary criticism, and takes on a specific interest when we consider it in the context of relevance theory, as a theory of communication (Sperber and Wilson, 1986). Communication is governed by the principle of relevance, which guarantees that if greater processing effort is demanded (e.g., by a text) then there will be greater cognitive effects. The key cognitive effect is that an implicature is produced. When a meaning is implied by a text it is an implication. A subset of implications are implicatures: an implicature is a communicated implication, and the derivation of implicatures by an audience is a derivation of implications which they take the author to be communicating. Thus the generation of a wider range of implicatures increases the range of what the audience can assume is being communicated by the text. Markedness produces implicatures. The unpredictability of markedness characteristically demands greater processing effort, and thus should always demand of the audience a greater degree of inferencing leading to a wider range of implicatures than would be demanded by an equivalent unmarked text. Because literary texts have added form, and because added form always permits the emergence of markedness, literary texts thus encourage their audiences to draw a wider range of implicatures.

Attenuated Linguistic Form in Literature

Literary texts can thus have 'more form' than ordinary language (lineation, meter, rhyme, etc.) but on the other hand, literary texts can also have 'less form' than ordinary language, generally by virtue of the literary text having an attenuated syntax. Thus, for example, Lorimer (1954: 548) describes (Persian) Bakhtiari verse, saying: "the language is frequently reduced to a sort of telegraphese, in which words or phrases are frequently juxtaposed without any nexus, or often any predicate." Something similar can be seen in this stanza by Blake:

> And what shoulder, & what art,
> Could twist the sinews of thy heart?
> And when thy heart began to beat,
> What dread hand? & what dread feet?
> William Blake 'The Tyger' (Blake's punctuation).

Attenuation of syntax can emerge in literary texts through concatenation, listing, the omission of conjunctions, a dispreference for complex sentence structures (e.g., fewer embedded clauses), omission of other syntactic units ('ellipsis'), and a greater freedom of reordering of elements within the clause.

Where syntax is attenuated, the text as code is attenuated, and so the text codes less meaning: that is, logical forms or propositions are less easily decoded from the syntactic organization of the words. Bloch (1974) proposed that attenuated syntax was a characteristic of ritual language (which is often one of the subtypes of verbal art), and he suggested that attenuated form in ritual language functions as a means of control by authority: "ritual is a kind of tunnel into which one plunges, and where, since there is no possibility of turning either to right or left, the only thing to do is to follow." However, this overemphasizes the degree to which the syntax of a text determines what it communicates: as we know from pragmatic theory, what the text codes is only partial evidence for communicated meaning, but meanings can be inferred from other kinds of evidence associated with the text in a cultural context. Attenuated form can liberate rather than limit interpretation, by demanding greater inferential activity from the audience (for a general discussion of theories of ritual speech, see Keane, 1997).

The syntax of verse can be attenuated relative to ordinary syntax, but it can also violate principles of ordinary syntax, either by its extreme attenuation, or by reorderings of words or phrases in ways which are not normally permitted. Examinations of these radical reorderings include Austin (1984) on the syntax of English Romantic poetry, or O'Neil (2001) on the very radical reorderings found in medieval Icelandic poetry, and these accounts usually conclude that where syntactic rules or conditions are broken, they are not broken randomly, but are broken in ways which specifically refer to the underlying linguistic forms of the language (for more discussion *see Hanson chapter*). More generally, there is a view that where the syntactic (or phonological) form of literature varies from ordinary language, it varies in a way which is dependent not only on general linguistic principles, but on the specific principles of that language. (For critical discussion of the possibility that literary language is a development of ordinary language, see Fabb, 2010.)

The Processing of Literary Linguistic Form

There are two broadly distinct processing tasks in producing or receiving language, which we might distinguish as coding and inferencing. As far as the hearer or reader is concerned, the coding tasks involve the identification of the sound-structure of the utterance, identification of words, of syntactic relations between words, and thereby producing a sentence structure which codes a 'logical form,' from which propositions can be derived. The inferencing tasks take the propositions coded by the sentence as partial evidence of the communicator's intention, add other propositions drawn from memory, and develop implicatures (implications which are intended by the communicator) from this. In the coding stage of processing, the verbatim text must be identified (i.e., the actual sounds, words, order), but only in order to determine the logical form, or gist, of the linguistic input; the gist may be retained in memory but there is little reason to retain a memory of the verbatim form, or to focus on the verbatim form as such. However, (following Jakobson) we can say that in literary texts, we are expected to focus on the verbatim form, for reasons discussed earlier.

It is likely that in addition to extracting the coded meanings from a literary text, some cognitive process assigns specific literary forms to the verbatim text, whether regular or irregular. For example, when reading or listening to Dryden's text, the alliteration in the line may be specifically identified by the processor as a pattern, as are the meter and rhyme pattern which hold throughout. The literary formal patterns which the processor may identify are based on the verbatim text. This raises interesting questions for working memory, which I now consider, using the model of Baddeley and Hitch (Baddeley, 2012). In this model, the seen or heard linguistic input is integrated with knowledge of language (phonology, syntax, etc.) into structured verbatim linguistic material, in working memory (in the Baddeley–Hitch model, this is done in a subpart of working memory called the episodic buffer, which integrates material). Only a small amount of material can be held – about 15 syntactically connected words; this can be understood by hypothesizing that working memory can hold about four chunks or episodes: when holding language, those chunks might be individual unconnected words, but if the words are connected then several words can be combined into a single chunk. When we listen to language, this limited amount of material is constantly replenished as new material comes in and old material is lost. In verse, many of the added forms (particularly the regular added forms) hold relative to the line or in some cases a pair of lines: meter regulates the whole line, rhymes tend to be placed in specific positions relative to the line, alliteration stretches across a line, parallelism holds between half-lines or between whole lines, and so on. This suggests that if these added forms are to be processed, the line must be treated as a whole unit, verbatim, in working memory. We might begin with the position that words are fed in a continuous stream into and out of working memory capacity in ordinary language. In contrast, the hypothesis is that verse is processed quantally, line by line, with the first word in a line held in working memory until the whole line is processed. Once processed, the line as a whole can be dispensed with (perhaps retaining the final word in memory as a rhyme). The view that the line is treated as a whole unit in working memory is usually based on the fact that the line is sufficiently short that a whole line could be contained verbatim within working memory capacity (Hogan, 1997; Fabb, 2014). In fact, where lines are short, pairs of lines might be treated as whole units, and this would make sense in those traditions where parallelism between lines is strictly regulated and must be processed as such.

The evidence that the formal patterns in the verbatim text must be specifically processed alongside the decoding for gist comes from experimental work on processing ease and memory. We know that regular forms make the processing of the language easier (Reber et al., 2004), at least in part because the forms restrict the selection space for words. In processing language, the hearer must discover what word is being spoken, which involves matching the sound input to the known word. The retrieval of the known word is made easier when the candidates are more restricted: that is, when the selection space is restricted. For example, in Blake's text the hearer knows that the fourth line must end in a word rhyming with 'beat.' This means that the rhyme means that the word 'feet' can more easily be drawn from the lexicon to match the sounds which are heard (and thus to recognize that those sounds code that word). Another kind of evidence that formal patterns must be specifically processed comes from the fact that when an alliterating pattern is repeated later in the text, words adjacent to the earlier pattern prime the selection of words adjacent to the later pattern (Lea et al., 2008). These experiments show that verbatim form must be specifically processed, alongside processing for gist, because it has an influence on the decoding process.

Why should it be interesting that lines are treated as a whole verbatim unit in working memory? This is a claim which has been made before, in various guises, and usually it is a claim which suggests that conscious attention is focused on the line, that the contents of the line, separated off from the text, are given a privileged status, presumably with affective and epistemic consequences. These claims remain untested, but fit well with traditional views of literature, thus matching newer cognitive and linguistic approaches with more traditional conceptions of poetry (see, for example, Boyd, 2012: 41).

Issues of form and working memory usually arise for verse, but it is worth asking what interest they have for literary prose. We know that literary prose can also have added form, including, for example, alliteration, rhyme, parallelism, and rhythmicity, though these forms are usually irregular (in part because regular form depends on lineation to provide frames against which the regularities can be formulated). It is likely that literary prose also requires attention to the verbatim language of the text, but in the absence of lineation, this raises unanswered questions about how prose is handled by working memory capacity.

The Assignment of Form by Inferencing

There is good reason to think that forms are assigned to the linguistic material being processed during the early stages of processing (alongside the decoding process), presumably by technical means similar to the ways in which linguistic form is assigned to the material. Indeed, the possibility *(Kristin*

Hanson chapter, Language and Poetic Structure) that some of this processing of form depends on underlying linguistic form fits with the possibility that the processing of linguistic form is closely connected with general phonological, lexical, and syntactic processing. However, these stages of processing are not characteristically open to introspection, and so we must also consider the fact that literary form – unlike linguistic form generally – is often quite salient, being explicitly recognized as such by the audience. This is best handled by suggesting that form can be assigned in a second way to the text, by inferencing (Fabb, 2002). For example, in Dryden's text cited above, the identification of alliteration is a specific part of the covert processing of the text (irrespective of whether it is explicitly noticed), and at the same time may be explicitly recognized as alliteration by the literarily competent audience. That is, the hearer or reader may draw the implicature that 'this line alliterates,' based, as with all implicatures, on the evidence provided by the text in a context. Similarly, the audience can produce explicit thoughts about the text that 'it rhymes,' 'it is in iambic pentameter,' 'it is in heroic couplets,' and so on. Form thus holds of the text as the content of an implicature (about the text) for which the text provides evidence. Two interesting consequences follow from focusing on form as implicated. First, it means that like the content of any implicature, form can be vague, ambiguous, or contradictory; in principle, form can even be 'metaphorical' – a form may be implied for a text which is difficult to literally assign to it. Second, it means that by treating form as a content, we can better understand the close interaction of form and content in a literary text, how forms can be symbolic, and so on.

Narrative and Language: Representation and Engagement

In this section, I comment on three aspects of narrative where there are issues of specific linguistic interest.

As Labov and Waletzky (1967) noted, narrative is defined by sequence, where verbal sequence mimics event sequence: the most minimal narrative represents an event leading to another event, and in verbal narratives the clause representing the first event precedes the clause representing the second event. An important way in which language functions in narrative relates to the narrative as a sequence, and how the sequence is divided into subsequences. The subsequencing operates at different levels. At the highest level, a narrative characteristically represents a complication (e.g., something goes wrong) which is resolved (e.g., it is put right), and the moment of shift between these often involves linguistic markedness, for example, a repetition, or some unexpected form or pattern (this is the moment of 'evaluation' of the narrative for Labov and Waletzky, 1967). This markedness appears to function to draw the audience's attention to this most important point in the story. At an intermediate level, longer narratives tend to be composed of distinct episodes (each usually with its own demarcated time, place, and participants), and episode boundaries are characteristically linguistically marked, for example, with a distinct connective such as 'so' or 'then,' by a shift of tense, or some other linguistic change whose semantic content may be neutralized or de-emphasized in favor of the structural function of marking a boundary (Hymes, 1981). At the sentence level, narratives make a distinction between clauses which express the sequence of events and clauses which indicate context or circumstance for events; the former are called 'storyline clauses' and are characteristically linguistically distinctive, for example, having a higher level of transitivity (in an extended sense of transitivity based around an actor making a change to another actor or thing, the basis of many narratives; Hopper and Thompson, 1980).

Another aspect in which language functions interestingly in narrative is in how the language enables the reader to keep track of which represented people are involved in events, and the sequencing and location of those events. This involves linguistic analysis of the use of pronouns, tense, and time markers, and other deictic items, to investigate how readers construct a mental representation of a fictional world (Emmott, 1997). As with all aspects of literary language, literary narrative can break or bend the expected rules, to produce particular effects. Thus, consider the way in which Charlotte Brontë begins *Jane Eyre*, by referring to location, time, and participants in a way which suggests (impossibly) that they are already part of the reader's mental representation of the narrated world.

> There was no possibility of taking a walk that day. We had been wandering, indeed, in the leafless shrubbery an hour in the morning; but since dinner (Mrs. Reed, when there was no company, dined early) the cold winter wind had brought with it clouds so sombre, and a rain so penetrating, that further out-door exercise was now out of the question.
>
> I was glad of it: I never liked long walks, especially on chilly afternoons: dreadful to me was the coming home in the raw twilight, with nipped fingers and toes, and a heart saddened by the chidings of Bessie, the nurse, and humbled by the consciousness of my physical inferiority to Eliza, John, and Georgiana Reed.
>
> Charlotte Brontë *Jane Eyre*, chapter 1 (first two paragraphs).

The same event can be represented by different types of syntactic construction: by an active or passive sentence, by a noun phrase, and so on. The choice between these can either emphasize or de-emphasize the role of actors in an event. In the second paragraph of the text above note the use of 'the coming home' (not: I came home) and 'a heart saddened' (not: my heart saddened). In both cases, the narrator, Jane, goes unmentioned as an agent or a possessor/experiencer, in a verbal echo of her more general removal and marginalization in the represented world of the novel. The analysis of how events are represented by different 'choices' within the linguistic system – both choices at a syntactic level and more generally in ways of speaking or stylistic choice – often forms part of a critical theoretical account of society, power, and inequality, often in media language rather than strictly literary language, and in this case is part of critical discourse analysis (Fairclough, 2010).

A third aspect of language which is of particular interest in narrative relates to the factuality or reliability of the represented events. In many types of narrative, events are represented by mediating them through a fictional character, who may or may not be explicitly represented as the narrator. Narrators may use the language of the text to indicate that events are

being mediated through an observer. Thus in the following text, the events are partly narrated by an (presumably reliable) external narrator, and partly narrated from the point of view of (the less reliable) Elizabeth herself.

> And with these words he hastily left the room, and Elizabeth heard him the next moment open the front door and quit the house.
> The tumult of her mind, was now painfully great. She knew not how to support herself, and from actual weakness sat down and cried for half-an-hour. Her astonishment, as she reflected on what had passed, was increased by every review of it. That she should receive an offer of marriage from Mr. Darcy!
>
> Jane Austen Pride and Prejudice ch.34.

The use of the combination 'was now' is particularly interesting (and common): it represents the events both as in the past (was) from the external narrator's point of view, and in the present (now) from the character's point of view. The reader is perhaps caught in both these perspectives at the same time. Linguistic devices of this kind for mediating the representation of events, and putting the reader or listener into a complex conspiracy with the characters, are common in literature (Banfield, 1982).

Effects of Language in Literature

From the perspective of literary studies, the primary interest in the language of literature is in the effects that specific kinds of language choices have on the reader or listener. In particular, can we explain why literature is characteristically valued as a way of using language? One possibility has already been explored, which is that language is used to produce markedness: a norm is set and then violated or varied from, thus requiring particular processing effort in the audience, which in turn delivers a wider range of interpretive effects. Thus the forms of language produce a wider range of meanings.

A sequence of psychological experiments have shown that various manipulations of language which are characteristic of literary texts can produce effects of truth or familiarity or pleasure. Thus McGlone and Tofighbakhsh (2000) show that aphorisms which rhyme are considered to be truer than aphorisms which do not. Reber et al. (2004) show that all kinds of regular poetic forms make language processing easier, and that the easing of processing can produce as side effects the sense that what is coded by the text is more true, is familiar (even if it is in fact novel), and is liked more. Thus the regular forms of language in literature appear to have an inherent capability to produce these epistemic and aesthetic effects.

Related questions may arise about other aspects of language in literature. For example, Rhodes and Donaldson (2008) show that syntactic contexts which result in the pairing of two words can produce the effect of 'unitizing' those words, as though they are a connected pair (even when they are not strictly related in meaning). This in turn can produce the effect of familiarity, as though this pair is already familiar (even when it is not). Though this is another quite low-level epistemic effect, it may nevertheless constitute a characteristic effect of the frequent use of parallelism in literature. Thus in Dryden's text quoted earlier, a parallel structure creates a pairing of 'praise' and 'blame' (already quite familiar in its own right) but also creates a pairing of 'dowdies' and 'deformity' which in itself is quite novel. Nevertheless, psychological work on unitization suggests that this pairing may produce a small 'epistemic jag,' a small effect of familiarity in the reader, which perhaps contributes to the overall aesthetic effect of the text (the term adapted from 'arousal jag,' Berlyne, 1960).

Finally, it is worth asking whether aspects of the language of literature encourage or enable creativity in authors. The processing of added literary form, in both verse and prose, appears to operate alongside ordinary language processing. Syntactic structure matches neither the line nor the limits of working memory (syntactic processing depends more indirectly on working memory, not requiring, for example, each sentence to be processed as a whole). The imposition of other types of form on the language of literature raises questions about the composition of literary texts. Fabb (2009) suggests that literary texts (and particularly verse) may in some cases be composed by concatenating verbal material rather than generating it through the normal syntactic processes. More generally, it is worth asking whether literary composition interferes with ordinary language production in ways which give rise to kinds of inventiveness, formal surprise, and creativity characteristic of literary composition.

Language and Poetic Structure

Abstract

A fundamental relationship between language and poetic structure is that between grammar and verse forms such as meter, rhyme and alliteration, and syntactic parallelism. Like a speaker of a language, a poet composing in such a verse form has intuitive knowledge of a finite system of constraints which defines the form, within which infinitely many various and new instances of the form can be created. Research making such knowledge explicit has revealed just how directly such forms draw on grammatical structure, inspiring and supporting an explicit cross-linguistic theory of verse forms relating them to universal grammar.

Language is the material out of which poetry is made. It is a complex phenomenon, having a characteristic structure involving a lexicon and a grammar with both phonology and syntax, as well as characteristic uses such as communication. All of these aspects of language play interesting roles in poetic structure. This article will focus mainly on grammar, and its relationship to characteristic aspects of poetic structure such as meter, rhyme and alliteration, and syntactic parallelism. These define core forms of versification found across the world's languages (Jakobson, 1960; Kiparsky, 1973, 1987; Fabb, 1997) and create poetic effects even when they are not used with sufficient regularity to constitute versification. In recent decades they have been the subject of striking new directions of research as a result of new directions of research in grammar.

Grammar and Verse

Versification by definition imposes formal constraints on language beyond those language conforms to intrinsically. To describe those constraints for any given verse form is a surprisingly challenging problem, because individual lines within a form are all different from one another, often artfully so for specific effects. It is thus a problem, as Jakobson (1960) influentially put it, of abstracting the invariant 'verse design' from the variation embodied in all the 'verse instances.' Even for those verse forms, especially in written traditions, for which some constraints have been articulated, the problem remains a challenging one, in that poets' actual practice may not match the articulated constraints: lines which violate them may be included in compositions in the form, at the same time that lines which conform to them may never be used. Such mismatches suggest that articulated constraints may not constitute a complete and true description of what a poet instinctively knows about a form.

Construing the problem of describing a verse form as one of making explicit unconscious as well as conscious knowledge a poet has of what defines the form makes it, as Halle and Keyser (1972) point out, analogous to the problem of describing grammar itself. In Chomsky's (1965, 1972) influential formulation, grammar is knowledge a fluent speaker of a language has, partly consciously and partly unconsciously, of what would or would not be well-formed instances of the language. In phonology, for example, the subsystem of grammar dealing with sound structure (*see* Phonology), an English speaker knows not only that the combination of sounds in *brick* is an actual word and that in *blick* is not, but also that *blick* is a possible word whereas **bnick* is not; the '*' indicates the latter's ill-formedness. Similarly in syntax, an English speaker knows that a sentence like *Colorless green ideas sleep furiously* is a possible sentence of English while **Furiously ideas green colorless sleep the* is not. To describe the grammar of a language, Chomsky argues, is to make explicit the constraints which constitute such knowledge. The research program within linguistics which adopts that goal is 'generative linguistics' (*see* Generative Grammar), and its analog for verse is 'generative poetics.'

Describing a verse form involves grammar in substantive aspects as well. Although meter, rhyme and alliteration, and even syntactic parallelism are often described metaphorically as contributing 'music' to poetry, the entities which define them – particular configurations of vowels and consonants, syllables and stress, noun phrases and verb phrases – are specific to grammar. This means that as research into grammar has sought to discover the fundamental entities and organizational principles of grammars, new formal structures have become available to descriptions of verse forms, sometimes leading to striking new insights into familiar forms. By the same token, research into verse forms has suggested and supported hypothesized entities and principles of grammar.

Two ideas which have shaped grammatical research have been particularly significant for research into versification. One is the assumption, articulated by de Saussure (2006) and continued in generative grammar, that grammar is at some level purely formal: phonology is not reducible to sound, and syntax is not reducible to meaning. The entities of grammar defining verse forms may thus sometimes prove to be surprisingly abstract.

The other is the conceptualization of the grammar of any particular language as one instance of a common phenomenon of human language. Although this idea also has a long history, including notably for poetics the interest in it taken by Jakobson and his circle (Toman, 1995), it was given a particularly galvanizing (though not uncontroversial) formulation in Chomsky's (1965, 1972) suggestion that the most basic formal properties of grammars might be essentially similar across all languages because they are innately determined (see also Pinker, 1994). This hypothesis of 'universal grammar' motivates the relevance of wide-ranging cross-linguistic phenomena to the formalization of any single language's grammar. For

versification, this means that evidence for particular ways of analyzing the structures figuring in a verse form may come from languages unrelated to that of the verse in question, and it means that perception of some aspects of verse may be as much instinctive as learned (Kiparsky, 1987).

The observation that the goals and vocabulary of the description of verse are similar to those of the description of grammar invites the deeper question of whether there can be a theory of versification, as there are theories of grammar, and if so, what specific relationship of versification to grammar such a theory might posit. After all, there are differences as well as similarities: we can usually tell in an instant whether language is verse or not. Again it was Jakobson (1960) who influentially suggested that it is specifically the sequencing of entities which are in some way equivalent in language which constitutes verse. Interpreting this in light of the formal and universalist understanding of grammar characteristic of generative theories, Kiparsky (1973, 1987) ventured one of the first testable theories of versification, hypothesizing that verse forms are constituted by repetition of those phonological and syntactic structures which figure in universal grammar. What these structures are and how they are organized may be different in important ways from what Jakobson assumed, however; for example, the linear sequencing he emphasized is crucially understood within generative theory to interact with hierarchical structure.

One of the simplest observations in support of this hypothesis about the relationship of verse to grammar is that each of the major forms of versification corresponds to a major subsystem of grammar. Let us turn, then, to some specific examples of descriptive and theoretical claims following this line of inquiry, and then briefly consider some of its consequences and limitations.

Meter

The phonology of every language involves two distinct though interrelated subsystems, one dealing with rhythm, such as the quantitative grouping of sounds into stressed and unstressed syllables, and the other dealing with what is sometimes termed 'melody,' referring not only to tones but also to the qualitative features of segments which make, for example, a [p] different from a [b] or an [i] different from an [e]. Verse forms which impose constraints on rhythmic structure beyond those given by the phonology are meters.

The dominant meter of the modern English poetic tradition, the iambic pentameter (from Greek ἰαμβικός πεντάμετρος, a line of five iambs, metrical feet of two syllables, one 'short' then one 'long'), affords a well-developed example of how changes in the goals and substance of grammatical description have wrought changes in the conceptualization of a familiar verse form. The English iambic pentameter has a long tradition of being described as a line having a basic form of five iambic feet (in (a) separated by '|'), each consisting of an unstressed syllable ('x') followed by a stressed one ('/'):

a. x / | x / | x / | x / | x /

What 'unstressed' and 'stressed' mean in this context are matters of debate, but a line like (b i) below plausibly has a rhythmic pattern similar to (a) on most interpretations. Other lines, however, like (b ii) cited in Kiparsky (1975), vary from the pattern in (a) and are felt to be more complex. Variations as in (b ii) are, in this tradition, described as involving 'substitution' of different kinds of feet with different patterns of syllables and stress for the basic iambs of (a), such as trochees ($^{/x}$), spondees ($^{//}$), phyrrics (^{xx}), or anapests ($^{x\,x\,/}$), as shown:

b. x / |x / | x / | x / | x /

i. So long as men can breathe and eyes can see
(Shakespeare, Sonnets 18, 13)

/ x| / / | x x| / /|x /

ii. Pluck the keen teeth from the fierce tiger's jaws,
(Shakespeare, Sonnets 19, 3)

x /| x x /|x x |x /| x x /

iii. How many a holy and obsequious tear
(Shakespeare, Sonnets 31, 5)

What Halle and Keyser, building on Jespersen (1933), point out is that unless such a description makes explicit not only what substitutions are found, but also what ones are not found, it fails to capture what the poet knows that leads to use of some variations but avoidance of other imaginable ones, by hypothesis on grounds of their metricality and unmetricality, respectively. The construct in (c), for example, sounds like prose, not verse, and in spite of its 10 syllables has a rhythmic structure not found in any lines in Shakespeare's sonnets. Yet as shown, it can be analyzed into basic and substituted feet just as the lines in (b) can; nothing in the traditional description of iambic pentameter captures (c)'s fundamental difference of unmetricality:

c. x / |x x|x / | x x|/ x

*Imaginable lines are avoided (construct).

An adequate description of a meter, Halle and Keyser suggest, should model a poet's intuitions regarding metricality as well as complexity.

Much research has gone into the question of how to realize this goal. Most fundamentally, Halle and Keyser (1972) suggest that a meter must be formally distinguished from phonology. As language, a line of verse has a rhythmic structure defined by phonology (Chomsky and Halle, 1968), regardless of any meter. For the English iambic pentameter, they suggest, the meter itself can be formalized in two components: an abstract template composed of weak ('w') and strong ('s') metrical positions; and correspondence rules defining allowable mappings of the phonological structure of the line into the template. A scansion is, then, not a representation of a stress pattern, but a mapping of a stress pattern – or more precisely, of a phonological form which is realized as one – into the template in accordance with the rules. And the challenge for a description of a meter is to specify the right template and correspondence rules.

For example, Kiparsky (1977), building on insights of Liberman and Prince (1977) that linguistic rhythm itself involves w and s positions which form constituents ('⋀'),

proposes that at its lowest level the English iambic pentameter has a template of five feet as in (d):

d.

One correspondence rule maps one syllable into each position, as stated in (f i) below. As for stress, Kiparsky (1975, 1977) argues that Shakespeare avoids lines like the imaginable (e) which is rhythmically similar to (b ii) but has polysyllabic words where (b ii) has monosyllables:

e. *Pluck imménse teeth from enráged tigers' jaws (construct)

This contrast suggests that it is specifically stress relations within words that the meter regulates, as expressed informally in the correspondence rule in (f ii):

f. i. Each metrical position corresponds to a syllable.
ii. No weak metrical position corresponds to a syllable which is strong relative to another syllable in the same word.

Such a model of the iambic pentameter describes the lines in (b) as metrical. In (g) the stress regulated by (f ii) is marked, and as (g i, ii) show, the lines in (b) can be mapped into the template in (d) in accordance with (f). The model describes the lines in (c) and (e), in contrast, as unmetrical; as (g iii, iv) show, they cannot be mapped into (d):

g. i. So long as men can breathe and eyes can see

ii. Pluck the keen teeth from the fierce tíger's jaws

iii. *Pluck imménse teeth from enráged tígers' jaws

iv. *Imáginable lines are avóided

The model thus posits a verse design that allows a varied range of rhythmic structures in its verse instances, but not an unlimited one. Moreover, it does so in a way that establishes for each line an explicit relationship between its phonologically defined rhythmic structure and a metrical template, the relationship from which metrical effects arise.

The template in (d) and the constraints in (f) are only illustrative of basic elements of a description of the English iambic pentameter. There are systematic exceptions to (f) as well as additional strictures; there are phenomena of elision (reduction of two syllables to one used in (b iii)), extrametricality (extra syllables at edges), catalexis (unfilled metrical positions), resolution (multiple syllables in single metrical positions), caesurae (syntactic breaks within lines), and enjambment (absence of expected syntactic breaks at ends of lines) to be accounted for, not to mention refinements pertaining to stress itself. The details are different for every poet and genre (Kiparsky, 1975, 1977; Tarlinskaja, 1976); as Kiparsky (1977) observes, describing an individual poet's practice within a metrical tradition is analogous to describing dialects within a language. Shakespeare's claimed avoidance of lines like (e), for example, is categorical in his sonnets but not in his plays (Youmans, 1983; Golston, 1998; Hanson, 2006). And of course, English has meters other than the iambic pentameter, and languages across the world have other meters still.

Crucially, however, the goals, methods, and substance of generative grammar which shape the model in (d) and (f) have invited this metrical variety to be explored in a unified and grounded way. As noted, Kiparsky's (1977) formalization of (d) and (f ii) built on Liberman and Prince's (1977) theory of linguistic rhythm itself as composed of constituents pairing strong and weak elements, and further posited that those constituents are organized hierarchically to form a complex periodic structure of which stress patterns are one manifestation. That theory has inspired cross-linguistic studies of stress and revealed a rich range of structures and principles which figure in the grammar of rhythm (Hayes, 1995; Kager, 1999). Often inspired by and as well as inspiring metrics, this research has shaped further questions and answers arising from models like (d) and (f).

What, for example, are possible templates cross-linguistically? Hanson and Kiparsky (1996) suggest that templates stylize the rhythmic structure of language, and are therefore likewise composed of binary, headed constituents, though hierarchical organization of those constituents can produce surprising complexity; the iambic pentameter, for example, arguably has an inherently ambiguous template more like (h) than simply (d) (Kiparsky, 1977; Piera, 1981; Hanson, 1996, 2006 and others), with cola (groups of feet) and lines (groups of cola) themselves being constituents with a weak–strong form:

h. 
Fabb and Halle (2008) make similar claims about the hierarchical structure of the English iambic pentameter, though drawing on different phonological assumptions, using a different notation (the bracketed grids of Halle and Idsardi, 1995), and arguing for a different ontological status for the structure, with what functions like a template in their theory being generated by parsing of individual lines. Golston and Riad (2000) argue that templates are unnecessary, but only because, they argue, meters can be described directly through phonology.

What are possible correspondence rules? The familiar possibility of 'feminine endings,' the inclusion of an extra unstressed syllable at the edge of a line as in (i i), affords an early example of a metrical phenomenon inspiring a phonological analysis, specifically Hayes' (1981) now well-established hypothesis that in many languages a final constituent may be 'extrametrical' ('<>'), and left outside the basic groupings which define stress patterns. This allows reconceptualization of feminine endings as in (i i) as special correspondence rules grounded in phonology (Kiparsky, 1977); and a parallel reconceptualization of catalexis ('ø') as in (i ii) has followed suit (Kiparsky, 1991):

i. i. Make haste, the bridegroom he is come already

(*Romeo and Juliet* 4.4.27)

ii. ø Dead art thou! Alack, my child is dead,

(*Romeo and Juliet* 4.5.63)

More generally, the universal grammar of rhythm posits more entities than just syllables, including moras and phonological feet; more contrasts in prominence than just stress; and more ways that constituency matters to rhythm than just defining such contrasts (Hayes, 1995; Kager, 1999; McCarthy and Prince, 1993). Different ways have been suggested as to how all these combine in meters, sometimes with surprising results. For example, some forms of the modern English iambic pentameter permit 'resolution,' mapping of a pair of syllables into a single metrical position when stress and quantity are configured in particular ways, as in (j) (Kiparsky, 1977):

j. Where all the kindred of the *Capu*lets lie

(*Romeo and Juliet* 4.1.112)

Hanson and Kiparsky (1996) argue that an iambic pentameter with such resolution does not have correspondence rule (f i) mapping a syllable into each metrical position but rather a rule mapping at most a phonological foot into each, thereby relating it to other English meters permitting variation in syllable count, including Hopkins' Sprung Rhythm (Kiparsky, 1989), as well as to meters of Old English, Latin, Greek, Finnish, and other languages. All of these have different rules for stress placement than (f i), raising issues of formalization of that rule as well. From a different perspective, Fabb and Halle (2008) offer an account of resolution in Greek meters through rules that count moras. The development of an explicit theory of how the universal grammar of rhythm seeks to align edges of constituents (McCarthy and Prince, 1993) has similarly allowed traditional constraints on line endings and on placement of caesuras in meters of Greek, Serbo-Croatian, or French, for example, to be formalized as correspondence rules of a kind a grammar might posit (Hayes, 1988; Hanson, 2009; Hayes et al., 2012), and helped to explain why even in the absence of such rules in the English iambic pentameter, for example, different caesura placements have very different effects.

In sum, the universal theory of grammatical rhythm is so well-developed at this point (which is not to say agreed upon) that it has been possible to propose cross-linguistic theories of meter based on it. Hanson and Kiparsky (1996) derive unrelated metrical systems in English and Finnish from common principles; Deo and Kiparsky (2011) show how such principles shape metrical borrowing and change in Arabic, Persian, and Urdu; and Duffell (2008) and Ecke (2009) point to where they have shaped the history of the English metrical tradition. Fabb and Halle (2008) stands as the first book-length study to attempt to formalize meters across a range of languages including English, French, Spanish and Italian, Greek, Arabic, Sanskrit, Latvian, and Hebrew from a consistent theoretical perspective derived from generative phonological theory.

At the same time, while meter has become better understood through better understanding of grammatical structure, many open questions remain. For example, knowledge of a meter clearly includes recognition not only of the limits of well-formedness, but also of specific effects of metrical complexity that can be created within those limits (Halle and Keyser, 1972). How is that knowledge expressed in models like that in (d) and (f) (Youmans, 1983; Freidberg, 2002)? What role does the frequency of occurrence of particular structures play in the conceptualization of a meter as a whole (Gasparov, 1987; Golston, 1998; Hayes et al., 2012)? Interestingly, while such questions pose challenges for metrical description, they do not necessarily challenge the theoretical assumption of the close relationship of meter to grammar; rather, parallel questions have been posed about modeling grammar itself.

Finally, explicit metrical description and theory have brought renewed interest to the metaphorical characterization of meter as 'music.' The abstract rhythmic structures claimed for language are in important ways formally like those of music (Lerdahl and Jackendoff, 1983), and the problem of aligning language to a metrical template is in important ways like that of aligning it to a tune, or 'textsetting' (Liberman, 1975). Research into textsetting has helped explain metrical preferences, extend generative models of English meters from lines to stanzas (Hayes and MacEachern, 1998), challenge arguments for aperiodic meters (Deo, 2007), and reveal similarities and differences in meter and textsetting in languages from English, French, and Spanish (Dell and Halle, 2009; Rodríguez-Vázquez, 2010) to Tashlhiyt Berber (Dell and Elmedlaoui, 2008).

Alliteration and Rhyme

Meters interact with, but are formally distinct from, verse forms which impose constraints on melodic structure such as rhyme and alliteration (Hayes, 1988; Hanson, 2003; Ecke, 2009). While the latter are sometimes collectively referred to as 'sound patterning' (Fabb, 1997), the term is somewhat unsatisfactory since it is not clear why these forms have any better claim to be described as 'sound' than meter does, at the same time that sound is not really what any such forms involve, so much as phonological structure, as poetry in sign languages emphasizes. A more appropriate collective term for them, in light of the specific phonological structures they engage with, might therefore be '(poetic) melody,' parallel to '(poetic) meter.'

Again it was Jakobson (1963) who, in an influential analysis of Germanic alliteration, showed how explicit characterization of such forms can lead to discoveries about their relationships to grammar. In Old English verse, for example, syllables in certain positions must alliterate, beginning either with the same consonants, as in (k i), or with potentially different vowels, as in (k ii):

k. i. þa *m*iddangeard *m*oncynnes Weard ('Cædmon's
'then middle earth mankind's Guardian' Hymn')
ii. *e*ce Drihten *æ*fter teode ('Cædmon's
'eternal Lord afterwards made' Hymn')

Jakobson observes that no characterization of alliteration in terms of repeating sounds can generalize across this differential treatment of consonants and vowels, and Kiparsky (1968, 1973) characterizes it in terms of syllable structure instead (*see* Suprasegmentals). The most sonorous element in a syllable is its 'nucleus,' in English typically, though not always, the vowel; segments which precede the nucleus form the syllable's 'onset' while those which follow the nucleus form its 'coda.' The onset in 'trait,' for example, is [tr]; in 'rate' it is [r], and in 'ate' it is empty. Hence, the alliteration in (k) can be characterized as requiring alliterating syllables to have the same initial onset segment, a requirement vacuously satisfied in vowel-initial syllables which have no such segment.

While Germanic alliteration involves further complexities when variation in it across the tradition is taken into account (Minkova, 2003), Kiparsky's specification of its locus in terms of syllable structure stands as a model for parallel exploration of where repetition is required in other melodic forms. Assonance as in (l i), for example, would seem to require repetition in the syllable nucleus, and slant rhyme as in (l ii) to require repetition of the final segment in the syllable coda for some poets (Kiparsky, 1973) and in the syllable as a whole for others (Hanson, 2003):

l. i. Time let me hail and *climb*
Golden in the heyday of his *eyes*
(Dylan Thomas, 'Fern Hill')
ii. The lips of time leech to the fountain *head*
Love drips and gathers, but the fallen *blood*
('The Force that through the Green Fuse Drives Flower')

Full rhyme in its dominant form in English, though not in all forms, involves repetition in a domain which extends beyond the syllable to include segments in following unstressed syllables (Rickert, 1978):

m. i. Do not go gentle into that good *night*
Rage, rage against the dying of the *light*
('Do Not Go Gentle into that Good Night')
ii. Round the grief of the *ages*
Who pay no praise or *wages*
('In My Craft or Sullen Art')

That domain's best definition – possibly in terms of phonological feet, possibly in terms of phonological words – stands as an open question (Steriade, 2011), but one which has received recent attention especially in light of poets' exuberant engagement with it in hip hop and rap, not only in English but also in Japanese and other languages (Katz, 2014; Kawahara, 2007). Finally, even when syllable structure does not seem to be involved, as in the elaborate Welsh *cynghanedd*, a verse form in which consonant sequences are repeated in a specific order, other grammatical principles still seem to be involved, with Hammond (2012), for example, relating the form as illustrated in (n) to principles governing root-and-pattern morphology in Semitic languages, where a root like 'k-t-b' might occur with one set of vowels in the form *kataba* 'he wrote' and another in *kitaabun* 'book':

n. A*gwrdd drwst* | a *gerdda drá*w ('Y Gwynt')
'mighty commotion passing yonder'

Across the variety and complexity in which melodic repetitions defining verse forms are found in poetry, then, while much remains to be explored, what does not seem to be found is, as Kiparsky (1973, 1987) suggests, imaginable locations for them which would have no grammatical definition at all.

Poetic melody seems also to involve grammatical structure with regard to variation in what counts as repetition. In some forms, similarity rather than complete identity seems to suffice:

o. Deep with the first dead lies London's daughter,
Robed in the long fr*iends*,
The grains beyond age, the dark veins of her mother.
Secret by the unmourning water
Of the riding Th*ames*,
After the first death, there is no other.
('A Refusal to Mourn the Death, by Fire, of a Child in London')

Explicit description and theorization of such variation, too, has progressed in conjunction with key discoveries about melody in language. First, segments are not monolithic, but composed of distinctive features defining classes of segments (Trubetzkoy, 1969; Chomsky and Halle, 1968) (*see* Phonology). Second, those features' distribution and realization may be affected by their phonological context, so that individual lexical items' underlying phonological representations may not be their surface forms (Chomsky and Halle, 1968). These concepts have been invoked to explain melodic variation in a variety of ways, both in traditions where it is conventionally recognized and in ones where it is only more recently acknowledged. For example, in Irish, consonants are traditionally specified as belonging to

certain rhyme classes, and segments in corresponding positions in rhymes must belong to the same class; one such class is the voiced stops [b,d,g], so that *éc* 'death' (in which the 'c' spells [g]), for example, can rhyme with *bét* 'misdeed' (in which the 't' spells [d]) (Murphy, 1961). Malone (1987) shows that these same voiced stops are nasalized in certain contexts, making the rhyme class a clear instance of an equivalence in verse being one which figures in grammar. Moreover, these voiced stops can alliterate with nasalized stops in the same place, so that *bo* 'cow,' for example, may alliterate with *mban* 'white (gen.pl.).' Malone (1987) suggests that here, it is because the initial sound of the latter is underlyingly [b], even though the nasalization makes it different on the surface, that the two can alliterate, in an instance of a different way in which Kiparsky (1968, 1973) had suggested that poets' practice might reflect equivalences defined by grammar, namely, by being based on underlying phonological representations rather than on surface forms.

In English, variation in melodic forms has traditionally been criticized rather than codified; but in one of the earliest investigations from a generative perspective, Zwicky (1976) suggests that in rhymes of English rock lyrics, corresponding segments may differ by one feature, as [n] and [m] in Dylan Thomas' rhyme in (o) of *friends/Thames* differ in their place of articulation; he also notes that some segments may have no correspondents, as [d] does not in that same rhyme. Here too, focusing on individual poets' practices in the way studies of meter have done has revealed relationships with grammatical structure. Golston (1997), for example, relates the possibility of segments having no correspondents as used regularly in Bob Dylan's rhymes to generalizations about English syllable structure; and Hanson (2003) relates the possibility of featural differences like that between [m] and [n] as used regularly in Robert Pinsky's slant rhymes to parallel neutralizations in English grammar, where [n] and [m] are not distinguished before oral stops, for example, since nasals must be articulated in the same place as a following stop, as in *ramp, rant, rank* [ŋk]. Steriade (2003, 2009) argues that similar practices are found among Romanian poets even when no comparable neutralizations exist in the language, and suggests that, more generally, featural differences in poetic melody reflect the perceptual similarity of segments in certain positions, the same similarity which shapes both phonological alternations and historical alterations cross-linguistically.

Collectively, the foregoing ideas and the studies which support them suggest that melodic forms show a good deal of variety across verse instances in the same way that metrical forms do. Fully formalizing their verse designs, however, has generally received less attention, with fewer studies working out explicit models of possible complexities and their limits in the practice of individual poets, let alone characterizing them as variations on an overall tradition. A particularly interesting theoretical impetus to such studies has come, however, from cross-linguistic studies of reduplication. These systematic processes in which all or part of the beginnings or ends of words are copied to derive new words or forms of words were precisely what Kiparsky (1973) pointed to in support of his suggestion that the equivalences that define verse forms are those that figure in grammar, with the reduplicative Gothic past tense in (p i), for example, where 'ai' spells [ɛ], showing exactly the same pattern as the Germanic alliteration in (k ii), and rhyme involving similar parallels as in (p ii) (Yip, 1999):

p.	i.	Gothic past tense:	haitan 'call' slepan 'sleep' aukan 'increase'	hai-hait 'called' sai-slep 'slept' ai-auk 'increased'
	ii.	Chamorro intensives:	dankolo 'big' bunita 'pretty'	dankolo-lo 'really big' bunita-ta 'very pretty'

As the intricate variety of reduplication systems has begun to be studied and theorized (McCarthy and Prince, 1994; Inkelas and Zoll, 2005), cross-linguistic theories of poetic melody analogous to those advanced for meter have begun to be explored (Holtman, 1994), and poetic melody has begun to be recognized as a source of insight into reduplication as poetic meter has been for metrical phonology.

Syntactic Parallelism

Finally, not only phonology but also morphology and syntax define verse forms, through requirements of parallel structure from line to line (Jakobson, 1966). Especially influential for English has been the syntactic parallelism used in ancient Hebrew poetry (Alter, 2011), illustrated by the passage in (q) translated by Jakobson (1966):

q.	ʔitti with me	milləbanon from Lebanon	kallah bride
	ʔitti with me	milləbanon from Lebanon	tabo ʔi come!
	tasuri depart	mero ʔ from the peak of	amanah Amanah,
	mero ʔs from the peak of	sənir Senir	wəhermon and Hermon,
	mimmə¿onot from the lairs of		ʔarayot lions
	mehaŕ rey from the mountains of ('Song of Solomon' 4:8)		ń merim leopards!

Here the last two lines transparently repeat a common morphological and syntactic structure: the individual words differ, but the grammatical classes of their component parts and the wholes these form are identical: prepositions, plural nouns, etc.

Again, however, making the verse design explicit by specifying what, exactly, repeats in general raises interesting grammatical questions noted by Jakobson (1966) and reframed from an early generative perspective by Kiparsky (1973). The first two lines, for example, repeat individual words up until their last ones, which then differ, being the vocative *kallah* 'bride' and the imperative *tabo ʔi* 'come'; nonetheless,

these words share a function of direct address which entails morphological similarities, both being bare forms. The third and fourth lines also differ, in that there is a verb, *tasuri* 'depart' in the third which is absent from the fourth, and a conjoined noun in the fourth, *wəhermon* 'and Hermon,' which is absent from the third. From the point of view of syntax, however, conjunction (Conj) produces an instance of the same syntactic category of each conjunct on its own, conjunction itself being a form of parallelism; and in any case a preposition (P) which requires a noun phrase (NP) object will be indifferent to the internal structure of the noun phrase. Hence, in English, for example, 'from Mary' and 'from Mary and John' are identical at one level of structure as the rudimentary sketches in (r) show:

r.

Moreover, when clauses (S) are conjoined, if a verb (V) is absent from the surface structure of the second clause, the verb of the first will nonetheless be understood to be present in it at some level of analysis: in 'Mary ate fish and John meat,' for example, 'ate' will be understood as the verb of the second clause, suggesting that both clauses maintain a consistent syntactic structure roughly as in (s), where 'ø' represents the absent verb:

s.

Thus, syntactic parallelism like that between lines three and four seems to involve morphological or syntactic identity at a somewhat abstract level, one more complex than any linear repetition of words or phrases or their types.

On the hypothesis of Kiparsky (1987), that level should be one that morphological and syntactic theories must posit to account for grammatical knowledge itself, independent of any poetic practice. Perhaps because English poetry only rarely uses syntactic parallelism in a sustained way, this hypothesis has not been so fully explored in the scholarly literature in English as its counterpart has been for other verse forms. Syntactic parallelism is, however, used as a verse form in diverse ways in many diverse languages – alongside the Hebrew, Russian, and Chinese discussed by Jakobson (1966), for example, it is used in Finnish, Galician, and many Native American languages (Bright, 1984; Hymes, 1998). Coupled with more recent theories of syntax, therefore, it affords rich material for exploration.

Conclusion

Versification represents only one of many ways in which language contributes to poetic structure. Not just the grammar but also the lexicon may be the source of significant patterns of repetition, engaging complex structures in storage of items (Tsur, 1992; Pinker, 1994). For every subsystem of grammar which defines a verse form by constraining some element of that system, other elements of that subsystem, as well as elements of other subsystems, remain free to create poetic effects of other kinds: phrasal rhythms (Cureton, 1992), syntactic suspensions (Austin, 1984), and more. And even the most traditional elements of verse are not necessarily used pervasively as verse forms, but sometimes only fragmentarily, or in traditional terminology 'ornamentally' rather than 'structurally.' In Shakespeare's sonnets, for example, alliteration and syntactic parallelism come and go within a form versified by meter and rhyme, in a manner which is not fundamentally different from the way meter and rhyme come and go in poems of Eliot which are not versified at all (Hanson and Kiparsky, 1997). Even as only a limiting case, however, discoveries of the relation of versification to grammar provide remarkable evidence of how forms which seem the height of artifice may in fact be rooted in ways of perceiving which, if the hypothesis of universal grammar is correct, operate as naturally as vision or hearing (Fodor, 1983). Such discoveries have consequences for poetic effects of all kinds, whether traditional or innovative, pervasive or fragmentary, natural or genuinely artificial.

Perhaps more strikingly, the focus on versification here has not touched on such fundamental functions of language as communication (*see* Communicative Competence: Linguistic Aspects), which are particularly complex and interesting in the case of poetry (Fabb, 2002). To some extent, this reflects the observation that communication is not unique to language: it has been argued by Sperber and Wilson (1986), for example, that in ordinary language, the phonological and syntactic parsing of a sentence makes only a minimal contribution to what it actually communicates, which in fact depends on an open-ended, context-dependent process of general reasoning which, unlike the structural analysis of grammar, is common to how information of all kinds is interpreted. At the same time, however, there is at least one way in which versification invites its own kind of reasoning. As Wimsatt (1954) notes, the repetitions which constitute versification consistently invite the question of how whatever is designated by similar forms might themselves be alike. In this way, as Jakobson (1956) suggests, there is a metaphorical way of thinking inherent in poetic structure, which is not only a matter of its meaning, but also of its form.

Language and Social Class

Suzanne Romaine, Merton College, Oxford, UK

Abstract

Social class has occupied a central place in the study of language variation since the rise of the discipline of sociolinguistics during the latter half of the twentieth century. Sociolinguists have correlated sociolinguistic variables such as postvocalic /r/ (e.g., car) with social factors such as class, sex, style, age, etc. A major finding of urban sociolinguistic work is that differences among social class dialects are quantitative and not qualitative. Generally speaking, the use of nonstandard forms increases the less formal the style and the lower one's social status, with men's scores higher than women's.

Early Studies of Language and Social Class

Since the rise of the discipline of sociolinguistics during the latter half of the twentieth century, social class has occupied a central place in the study of language variation as a key factor offering important insights into social structure. Until the 1960s, most studies of variability were concerned primarily with regional variation or dialectology, following a tradition established in the nineteenth century. These studies concentrated their efforts on documenting the rural dialects which were believed would soon disappear. Only during the latter half of the twentieth century would the concern for status-based differences in language become a primary rather than a secondary focus, when sociolinguists turned their attention to the language of cities, where an increasing proportion of the world's population lives in modern times. The rise of urbanization is connected with an increase in social stratification reflected in linguistic variation.

Research focusing on social dialects is sometimes referred to as social dialectology and occupies a central place in quantitative sociolinguistic research on urban speech varieties, beginning with William Labov's (1966) work in New York City. Although linguists were aware before of differences in language use tied to social class, Labov was the first to introduce a systematic methodology for investigating social dialects and produced the first large-scale sociolinguistic survey of an urban community. Earlier, for instance, Alan Ross (1954) suggested that certain vocabulary differences in English could be classified as U (upper class) or non-U (lower class), e.g., *serviette* (non-U) versus *table-napkin* (U), one of the best known of all linguistic class-indicators of England at the time. Labov, however, concentrating primarily on pronunciation differences, called phonological variables, showed how idiolects (or the speech of individuals) considered in isolation might seem random, but the speech community as a whole behaved regularly. Previous investigations had concluded that the speech of New Yorkers appeared to vary in a random and unpredictable manner. Sometimes they pronounced the names *Ian* and *Ann* alike and sometimes they pronounced postvocalic /r/ (i.e., *r* following a vowel) in words such as car, while at other times they did not. This fluctuation was termed 'free variation' because there did not seem to be any explanation for it. Labov's study and subsequent ones modeled after it, however, showed that when such free variation in the speech of and between individuals was viewed against the background of the community as a whole, it was not free, but rather conditioned by social factors such as social class, age, sex, and style in predictable ways.

Unlike previous dialectological studies, which generally relied on one person (usually an older male) as representative of a particular area, most sociolinguists choose a sample of persons with different social characteristics. Labov's survey was based on tape-recorded interviews with 103 people who had been chosen by random sample as being representative of the various social classes, ages, ethnic groups, etc. to be found in New York City. This approach solved the problem of how any one person's speech could be thought of as representing a large urban area. Thus, while idiolects (or the speech of individuals) considered in isolation might seem random, the speech community as a whole behaved regularly. Using these methods, one could predict that a person of a particular social class, age, sex, etc. would pronounce postvocalic /r/ a certain percent of the time in certain situations. Through the introduction of these new methods for investigating social dialects by correlating sociolinguistic variables with social factors, sociolinguists have been able to build up a comprehensive picture of social dialect differentiation in the United States and Britain in particular, and other places, where these studies have since been replicated.

Methods

In order to demonstrate a regular relationship between social and linguistic factors, we have to be able to measure them in a reliable way. Of the principal social dimensions sociolinguists have been concerned with (e.g., social class, age, sex, style, and network), social class has probably been the most researched. Patterns of social class differentiation are often assumed to be fundamental and other so-called sociolinguistic patterns of variation, e.g., stylistic and gender variation, are regarded as derivative of them. Many sociolinguistic studies have followed the generally accepted sociological practice of relying on indicators of social status such as education, occupation, housing, income, etc. to group individuals into social classes, and then looked to see how certain linguistic features were used by each group. The method used in New York City to study the linguistic features was to select easily quantifiable

items, in particular, phonological variables such as postvocalic /r/, which was either present or absent. This was one of the first features to be studied in detail by sociolinguists.

Results

Phonological Variables

Varieties of English can be divided into two major groups with respect to their treatment of postvocalic /r/: those that are r-pronouncing (rhotic) and those that are not r-pronouncing (nonrhotic). Today in Britain accents that have lost postvocalic /r/ as a result of linguistic change generally have more prestige than those, like Scottish English, that preserve it. In many parts of the United States the reverse is true, although this has not always been the case. Table 1 compares the pronunciation of postvocalic /r/ in New York City with that of Reading, England. The results show that in New York City the lower one's social status, as measured in terms of factors such as occupation, education, and income, the fewer postvocalic /r/'s one uses, while in Reading the reverse is true. Like many features investigated by sociolinguists, the pronunciation of postvocalic /r/ shows a geographically as well as socially significant distribution. There are also internal linguistic constraints affecting the realization of postvocalic /r/. New York City speakers pronounced /r/'s in word-final position (e.g., *floor*) more frequently than they did in word-internal position (e.g., *fourth*).

Just as the diffusion of linguistic features may be halted by natural geographical barriers, it may also be impeded by social class stratification. However, the boundaries between social dialects tend for the most part not to be absolute. The pattern of variation for postvocalic /r/ shows 'fine stratification' or continuous variation along a linguistic dimension (in this case a phonetic one) as well as an extralinguistic one (in this case social class). The indices go up or down in relation to social class, and there are no sharp breaks between groups. A major finding of urban sociolinguistic work is that differences among social dialects are quantitative and not qualitative.

Sociolinguists have studied many other variables in English and other languages that show similar sociolinguistically significant distributions. Peter Trudgill (1974a) found similar differences in Norwich in an urban dialect study modeled after the New York City research. Table 2 shows the results for three of his phonological variables: (ing), (t), and (h). The numbers show the percentage of nonstandard forms used by different class groups. The variable (ing) refers to alternation between alveolar /n/ and a velar nasal /ŋ/ in words with *-ing* endings such as *reading*, *singing*, etc. The lower a person's social status, the more likely he or she is to use a higher percentage of alveolar rather than velar nasal endings. This is often referred to popularly as 'dropping one's *g*'s', and is a well-known marker of social status over most of the English-speaking world, including New York City, where Labov also studied it.

Table 1 Percent of postvocalic /r/s pronounced

New York City	*Reading*	*Social class*
32	0	Upper-middle class
20	28	Lower-middle class
12	44	Upper-working class
0	49	Lower-working class

Adapted from Romaine, S., 2000. Language in Society. An Introduction to Sociolinguistics. Oxford University Press, Oxford, p. 68.

Table 2 Percent of nonstandard forms in Norwich

(*ing*)	(*h*)	(*t*)	*Social class*
31	6	41	Middle-middle class
42	14	62	Lower-middle class
87	40	89	Upper-working class
95	59	92	Middle-working class
100	61	94	Lower-working class

Adapted from Trudgill, P., 1974b. Sociolinguistics. An Introduction. Penguin, Harmondsworth, p. 48.

The variable (h) refers to alternation between /h/ and lack of it in words beginning with <h> such as *heart*, *hand*, etc. Most urban accents in England do not have initial /h/ or are variable in their usage of it. For these speakers who 'drop their *h*'s', *art* and *heart* are pronounced the same. Again, the lower a person's social status, the more likely he or she is to drop *h*'s. Speakers in the north of England, Scotland, and Ireland, however, retain /h/ , as do speakers of American English. The variable (t) refers to the use of glottal stops instead of /t/, as in words such as *bottle*, which is sometimes stereotypically spelled as *bot'le* to represent the glottalized pronunciation of the medial /t/. Most speakers of English glottalize final /t/ in words such as *pat*, and no social significance is attached to it. In many urban dialects of British English, however, glottal stops are more widely used, e.g., in London and Glasgow.

By comparing the results for the use of glottal stops in Norwich with those for (ing) and (h), some interesting conclusions can be drawn about the way language and social class are related in this English city. Looking first at frequency, even the middle class in Norwich uses glottal stops very frequently, i.e., almost 50% of the time, but this isn't true of (h). There is much more social stigma attached to *h*-dropping. Phonetician Alexander Ellis (1869) regarded *h*-dropping as tantamount to 'social suicide,' and more than a hundred years later J.C. Wells (1982: p. 254) described it as the 'single most powerful pronunciation shibboleth in England.' There is of course no reason to assume that every instance of variation in language will correlate with social structure in the same way or to the same extent. Most sociolinguistic variables have a complicated history, and the social significance of linguistic features may vary over time. Some variables will serve to stratify the population more finely than others, and some cases of variation do not seem to correlate with any external variables, e.g., the variation between /i/ and /ɛ/ in the first vowel of *economic* is probably one such instance. Phonological variables tend to show fine stratification and there is more socially significant variation in the pronunciation of English vowels than in consonants.

As in the case of postvocalic /r/, what is socially significant is how frequently a person uses glottal stops in particular linguistic and social contexts. The use of glottal stops is particularly socially stigmatized in medial position, e.g., *bottle*, *butter*. Glottal stops are more likely to occur according to the hierarchy of linguistic environments in Figure 1.

Figure 1 Linguistic environments for glottal stops.

Although all speakers are affected by the same internal constraints in the same way, they apply at different frequency levels, depending on social class membership and other external factors. Table 3 shows the incidence of glottal stops in relation to social class in Glasgow for all environments compared with that occurring only in medial position. Class I is the highest and contains professional people, while Class III is the lowest and contains unskilled workers. The results show that glottal stops are the norm for this community (74.3%) if we look at all the environments. Even the highest social class uses glottal stops nearly half the time and the lowest class, almost all the time. However, if we look at medial position, the highest social class uses no glottal stops in this environment, while the lowest class uses 68.8%.

The use of glottal stops has been noted as a feature of Glasgow speech since at least the late nineteenth century, but more recent sociolinguistic research shows that this feature is spreading from working-class urban speech, particularly that of London, and making rapid inroads into the speech of middle-class speakers in many other areas of southeastern England and Wales, and even as far as New Zealand, where it had not been heard before (Docherty et al., 2006). Hence, a feature once regarded as a vulgarism associated with the working class is becoming respectable (Wells, 1994: p. 201). Given its frequency in many areas of Britain across the social class spectrum, it would no longer be correct, strictly speaking, to classify this feature as nonstandard.

Grammatical Variables

Although grammatical variables have been less frequently studied than phonological ones, they have tended to show sharp stratification; that is, they often display a large social barrier between the middle class and the working class, as observed in the case of *h*-dropping. Table 4 compares the results of a study of a grammatical variable in Detroit and Norwich. The variable concerns the use of nonstandard third-person singular present tense verb forms without *-s*, e.g., *he go*. Only working-class speakers use these forms with any great frequency, and this is more often the case in Norwich than in Detroit. The gap between the middle- and working-class norms is also greater in Norwich than in Detroit, reflecting perhaps greater social mobility in the American social system. There are also other varieties of British English, e.g., in parts of the north, southwest, and south Wales, where the present tense paradigm is regularized in the opposite direction and all persons of the verb take *-s*, i.e., *I goes, you goes, he goes*, etc.

Another common grammatical feature of nonstandard English is so-called double or multiple negation, which involves the use of two or more negative elements where standard English requires only one. Compare nonstandard *he ain't got no money* with standard English *he hasn't got any money* or *he has no money*. This variable also has a long history going back centuries, but during the eighteenth century grammarians condemned the construction as nonstandard. The use of *ain't* has a similar history. This resulted in a decline in use of both *ain't* and multiple negation among the educated. In spite of correction by generations of teachers, both features have persisted in many nonstandard varieties. Table 5 shows the percent of multiple negative forms among African-American and white speakers in Detroit. There is sharp class stratification, with middle-class speakers regardless of race rarely using this feature. Overall, however, speakers of African-American English use multiple negation more frequently than whites.

Lexical and Discourse Variables

Sociolinguists have also extended the search for correlations between language and social class to encompass lexical and

discourse variables. Macaulay (2002), for instance, found that middle-class Scottish speakers in Ayr and Glasgow used adverbs ending in *-ly* (e.g., *slowly*) more than twice as frequently as working-class speakers. Other distinctions between the middle and working classes involved the use of *very*, which was almost exclusively a middle-class word, and *quite*, also used more predominantly by the middle class. There were also differences in the kinds of evaluative adjectives, with half of the adjectives used by the working class consisting of simple words of approval or disapproval such as *good*, *bad*, *nice*, etc. By contrast, the middle-class speakers used a wider variety of adjectives that were never used by working-class speakers, such as *horrible*, *messy*, *impressive*, *interesting*, *unattractive*, *fantastic*, *tremendous*, *impeccable*, and others. These differences are of a somewhat different nature than the ones previously discussed, where social class correlated closely with the boundary between standard and nonstandard usage. The higher incidence of adjectives and adverbs used by middle-class speakers served to emphasize the speaker's stance or personal viewpoint, while the working-class speakers on the other hand tended to leave their hearers to infer their point of view.

Studies such as these are also different in kind from Ross's early study of social class differences in vocabulary, where the variables investigated consisted of different words used to refer to the same thing, e.g., *lavatory* versus *toilet*. While some of the differences between so-called U (upper class) and non-U seem outdated and old-fashioned (e.g., U *looking glass* vs non-U *mirror* or U *wireless* vs non-U *radio*), and it has become increasingly common to think that access to higher education has increased social mobility and brought about a classless society, there is still considerable anxiety about social class and language in Britain. The issue of U and non-U language erupted in 2007 when Prince William broke up with then girlfriend Kate Middleton. The press speculated that perhaps she and her family, especially Kate's mother Carole, were just too middle class for the Royal family. Among Carole Middleton's linguistic faux pas the press commented on were her use of non-U *toilet* and *pardon* instead of *lavatory* (or the abbreviation *loo*) or *what*? Journalists speculated that perhaps a toilet had come between William and Kate, and headlines referred to a *toiletgate* scandal. Another linguistic misstep Carole Middleton made was to say 'Pleased to meet you' when she met William's grandmother, the Queen, instead of U 'How do you do?'

This incident indicates the enduring nature of linguistic insecurity and the divide between the upper and middle classes, despite the fact that some of the forms marking the boundary have changed. Today's non-U word or phrase may have been yesterday's U. *Toilet*, for instance, was a very smart word for the Edwardians, because it came from French, which was regarded as a prestige language. It went out of fashion, however, when their servants adopted it (compare also *serviette*, another term of French origin). Electronic corpora of modern English containing information about social class such as the British National Corpus can provide a handy way of checking the persistence of some of the social markers Ross mentioned (Romaine, 2008). The corpus contains one hundred million words of spoken and written British English from the 1990s. The spoken texts, comprising ten million words, include informal, unscripted conversation by speakers of different ages, regions, and social class. The British National Corpus categorized the speakers into four groups based on occupation: AB (top or middle management, administrative or professional), C1 (junior management, supervisory or clerical), C2 (skilled manual workers), and DE (semiskilled and unskilled manual workers). Although only 20% of the material in the spoken component of the corpus has been coded for speakers' social class, the corpus can still provide some insight into modern usage.

Table 6 shows the social distribution for *settee/couch/sofa* and *lounge/living room/sitting room*. The number of instances per million words is given for each term; boldface indicates the social group showing the highest usage for a particular term. The results show that social class differentiation in modern Britain is more nuanced than suggested by the simple division between U and non-U. While some words may distinguish the upper class from the rest, others may separate the working class from the lower-middle, or the middle-middle from the upper-middle classes. Ross, for instance, regarded *sofa* and *sitting room* as U and *settee* or *couch* and *lounge* as non-U. Looking first at variation in terms for the item of furniture, all four social groups use both *settee* and *sofa*; interestingly, the term *couch* does not occur for the highest and lowest social group. The lowest social group strongly favors the non-U term *settee*; the highest social group uses that term least. The term *sofa* occurs most frequently among class C2 followed by DE, but is less often used by two highest classes AB and C1. As for the room where this item of furniture is found, all social groups use all three terms. The middle and lower-middle classes (C1 and C2), however, are the greatest users of the supposedly non-U term *lounge*. The highest group leads in the use of the term *sitting room*, and the lowest in the use of the term *living room*. Thus, the upper class displays a tendency to sit on a settee in the sitting room, while the working class is more likely to sit on a settee in the living room, and the middle class to sit either on a sofa or couch in the lounge. These results display a rather mixed picture. While they appear to offer some support for the continuing U status of *sitting room* versus *lounge* and the non-U status of *settee* and *couch*, *sofa* does not appear to be an indicator of U status.

Often collocations, i.e., co-occurrences of words in context, are even more powerful indicators of social class than words in isolation. In 2012 the phrase *kitchen supper* triggered a national debate about class when Prime Minister David Cameron's Cabinet Office Minister remarked that the meals Cameron offered at his Downing Street flat to would-be Conservative

Table 6 Social distribution of *settee/sofa/couch* and *lounge/living room/sitting room* in the British National Corpus: hits/million words

Social class	*Settee*	*Sofa*	*Couch*	*Lounge*	*Living room*	*Sitting room*
AB	12.32	2.7	0	11.09	12.32	**13.55**
C1	18.02	2.57	5.5	32.18	9.01	9.01
C2	13.98	**8.39**	**8.39**	**48.93**	13.98	5.59
DE	**31.21**	4.46	0	8.92	**22.9**	8.92

p is less than or equal to .01; distribution is significant for *settee/sofa/couch*.
p is less than or equal to .001; distribution is significant for *lounge/living room/sitting room*.

donors were just 'kitchen suppers'. It meant relaxed, friendly meals in Mr Cameron's home rather than official dinners in a formal setting such as a Downing Street dining room. Terms for meals display social differentiation, with the evening meal typically referred to as *dinner* or *supper* by the upper class, but as *tea* by the working class, who use the term *dinner* for a midday meal. For the upper class *tea* is a late afternoon meal with sandwiches and baked goods like scones, and the midday meal is *lunch*.

Social Class Differentiation in Relation to Other Sociolinguistic Patterns

The intersection of social class and stylistic continua is one of the most important findings of quantitative sociolinguistics: namely, if a feature occurs more frequently in working-class speech, then it will occur more frequently in the informal speech of all speakers. There are also strong correlations between patterns of social stratification and gender, with a number of now classic findings emerging repeatedly. One of these sociolinguistic patterns is that women, regardless of other social characteristics such as class, age, etc., tend to use more standard forms than men.

Table 7 shows the results for the variable (ing) in Norwich in relation to social class, style, and sex. The scores represent the percent of nonstandard forms used by men and women in each social group in four contextual styles, i.e., when reading a word list, reading a short text, formal speech, and casual speech. Generally speaking, the use of nonstandard forms increases the less formal the style and the lower one's social status, with men's scores higher than women's. Although each class has different average scores in each style, all groups style-shift in the same direction in their formal speech style; that is, in the direction of the standard language. This similar behavior can be taken as an indication of membership in a speech community sharing norms for social evaluation of the relative prestige of variables. All groups recognize the overt greater prestige of standard speech and shift toward it in more formal styles.

Summing up these sociolinguistic patterns involving social class, gender, and style, sociolinguists would reply to the question of who is likely to speak most nonstandardly in a community: working-class men speaking in casual conversation. Conversely, middle-class women speaking in more formal conversation are closest to the standard. In Table 7, for instance, we can see that middle-middle-class women in word-list style never use the nonstandard form, while lower-working-class men use it all of the time. Note, however, that the differences between men and women are not equal throughout the social hierarchy. For this variable they are greatest in the lower-middle and upper-working class. Such patterns reveal basic linguistic fault lines in a community, and are indicative of the uneven spread of the standard and its associated prescriptive ideology in a speech community. Similar results have been found in other places, such as Sweden and the Netherlands (Nordberg, 2005).

Table 7 Social class, style, and sex differentiation in (ing) in Norwich

Class		*Style word list*	*Reading*	*Formal speech*	*Casual speech*
Middle-middle	M	0	0	4	31
	F	0	0	0	0
Lower-middle	M	0	20	27	17
	F	0	0	3	67
Upper-working	M	0	18	81	95
	F	11	13	68	77
Middle-working	M	24	43	91	97
	F	20	46	81	88
Lower-working	M	66	100	100	100
	F	17	54	97	100

Social Class Differentiation and Language Change

Because variability is a prerequisite for change, synchronic variation may represent a stage in long-term change. By examining the way in which variation is embedded into the social structure of a community, we can chart the spread of innovations just as dialect geographers mapped variation and change through geographical space. Sociolinguists have distinguished between 'change from above' and 'change from below' to refer to the differing points of departure for the diffusion of linguistic innovations through the social hierarchy. Change from above is conscious change originating in more formal styles and in the upper end of the social hierarchy, and change from below is below the level of conscious awareness originating in the lower end of the social hierarchy. Gender is a critical variable too. Women, particularly in the lower-middle class, often lead in the introduction of new standard forms of many of the phonological variables studied in the United States, the UK, and other industrialized societies such as Sweden, while men tend to lead in instances of change from below.

Because language, like fashion, is always changing, keeping up linguistically or sartorially with the proverbial Joneses is a never-ending task. Indeed, the Joneses may themselves decide to adopt once highly stigmatized features like the glottal stop, a behavior that has been referred to as 'linguistic slumming.' By contrast, in their effort to be linguistically correct, the middle and lower classes may hypercorrect and overshoot the norm of the group whose language they are aiming at, or use a false analogy resulting in an incorrect form. In the case of postvocalic /r/ in New York City, the lower-middle class shows the most radical style shifting, exceeding even the highest status group in their use of the standard forms in the most formal style. Another type of hypercorrection actually results in the production of incorrect forms. In New York City highly stigmatized pronunciations such as 'toity toid street' (for 33rd Street) are popularly associated with the so-called Brooklyn accent (although in fact are more widespread throughout working class speech of the city). Speakers who wish to dissociate themselves from this way of speaking often 'correct' forms containing the sound <oi>, so that *toilet* becomes *terlet* and *boil* becomes *berl*. Speakers alter these sounds because they are aware of the 'toity toid' stereotype, which suggests to them that <oi> is an incorrect pronunciation of <er>, so they correct all

cases where <oi> occurs to <er>. In cases like *terlet*, this produces a form that is not only hypercorrect, but also in fact nonexistent in the more prestigious form of speech that these speakers are trying to emulate. These hypercorrections often become so common that they too have now become stereotypes. People who drop *h*'s sometimes insert them in before words beginning with a vowel where they do not occur in the standard, resulting in hypercorrect forms such as *hextra* (*extra*), *hever* (*ever*), etc.

Hypercorrection happens because the behavior of the lower-middle class is governed by their recognition of an exterior standard of correctness and their insecurity about their own speech. They see the use of postvocalic /r/ as a prestige marker of the highest social group. In their attempt to adopt the norm of this group, they manifest their aspirations of upward social mobility, but they overshoot the mark. The clearest cases of hypercorrection occur when a feature is undergoing change in response to social pressure from above, i.e., a prestige norm used by the upper class. In New York City the new /r/ pronouncing norm is being imported into previously nonrhotic areas of the eastern United States. Hypercorrection by the lower-middle class accelerates the introduction of this new norm. The variable (ing), on the other hand, has been a stable marker of social and stylistic variation for a very long time and does not appear to be involved in change and hence does not display hypercorrection.

Alternatives to Social Class

Despite the successes of these investigations many sociolinguists have increasingly questioned the use of socioeconomic indices to determine speakers' class backgrounds and have explored alternative approaches to grouping people into discrete social classes based on indicators such as income, occupation, education, etc. This method assumes a consensus view of social class membership and that those in the same group will behave similarly. Some have argued, however, that social class differentiation is grounded in conflict rather than consensus. The concept of social class also applies more readily to western industrialized societies than to traditional rural village-based societies. Starting with the individual rather than the group allows us to overcome some of these limitations and to see patterns of variation and linguistic choices as a way of actively constructing social meanings and identities rather than merely reflecting membership in predetermined social categories.

Social Networks

One alternative to a class-based approach emphasizes the nature of contacts and networks in a society. Networks may cut across social class boundaries and reveal differences within social classes. Lesley Milroy's (1980) work in Belfast revealed important linguistic differences among working-class networks. Networks in which individuals interact locally within a well-defined territory and whose members are linked to each other in several capacities, e.g., as kin, neighbor, workmate, etc., act as a powerful influence on the maintenance of local norms. Two women, Hannah and Paula, who live in the same type of housing in the same area of Belfast and have similar employment, nevertheless, behaved quite differently from one another linguistically. Hannah is much more standard in her speech than Paula. The differences reflect their socialization patterns. Paula, whose speech is more nonstandard, is a member of a local bingo-playing group and has extensive kin ties in the area. Hannah has no kin in the area and does not associate with local people. In general, those with high network scores indicating the strength of association with the local community used more local, nonstandard forms of speech. Those whose networks were more open and less locally constrained used more standard speech.

Although there is a tendency for middle-class speakers to have looser networks than the working class, dense networks may also be found at the upper levels of society. The British upper class, for example, has been educated at elite schools and at Oxford and Cambridge, which has given rise to an equally distinctive speech variety that does not indicate their regional origins. More men than women had dense networks in Belfast, which suggests an explanation for some of the patterns of sex differentiation described earlier. The network approach has also been applied in non-Western settings such as Africa and Brazil. In Brazil, for example, it was used to study the extent to which rural migrants to urban areas assimilated to urban standard speech norms. Change has been slower for migrant women, who have fewer social contacts than men. The notion of network is potentially more useful than social class because it applies equally well to multilingual and monolingual settings.

Communities of Practice, Habitus, and the Linguistic Marketplace

Penelope Eckert's (2000) study of Jocks and Burnouts, two self-defined groups of high school students in Detroit, revealed that differing orientations to the school culture were correlated with opposing linguistic norms and styles of clothing. The Jocks aligned themselves with the middle-class values of the school and saw themselves as headed for college. The Burnouts oriented themselves to the local working-class world outside school, tended not to participate in school activities, and were not planning to attend college. Eckert situated her research within a theoretical framework drawing on notions such as community of practice and habitus. The concept of community of practice is closely related to that of social network. A community of practice shares ways of doing things, ways of talking, beliefs, and values. A habitus is a set of dispositions developed over the course of life through being embedded in a particular social position that influences patterns of behavior, affect, and thought. The notion of habitus is associated with the related concept of linguistic marketplace, both of which were developed by French sociologist, Pierre Bourdieu (1991). Linguistic practices function as commodities that are assigned value in a linguistic marketplace. Highly valued ways of speaking can be converted into actual economic capital by providing access to desirable career opportunities and employment. Conversely, nonstandard usage is an index of distance from or resistance to mainstream social and linguistic norms. The Burnouts, for instance, made significantly greater use of multiple negation than the Jocks, but a subgroup of

Burnouts (referred to as 'burned-out burnout girls') led the entire school, including burnout boys, in their use of this nonstandard feature.

These studies illustrate the importance of adopting a more dynamic view of language and of understanding how speakers use variable linguistic resources to construct identities in line with class-based language ideologies, i.e., beliefs and attitudes about language.

Abstract

The vocabulary, grammatical structure, and usage conventions of any language are linked in innumerable ways with the social, cultural, and historical experience of its speakers. Drawing on examples from many languages, this article demonstrates the nature and range of these links. It highlights the culture-specific nature of many words, including terms for social categories, emotions, and value concepts. It explains the notion of cultural key words and the significance of lexical elaboration. In the domain of grammar, the article shows how grammatical constructions and marking may express and reflect culture-related meanings. In the realm of language in use, topics considered include discourse particles and interjections, linguistic routines, speech genres and speech styles, and broader discourse styles, demonstrating diverse ways in which language use can be related to differing cultural norms, values, and attitudes.

Introduction

Every language provides its speakers with a unique, intricate, and constantly changing medium of expression. The structure of any language embodies a myriad of prepackaged meanings, a large proportion of which are language- and culture-specific, in two respects: first, in not having exact counterparts in other languages of the world and second, in reflecting, embodying, and helping to perpetuate a particular social, cultural, and historical experience. The purpose of this article is to demonstrate this in relation to three linguistic domains – words and phraseology, grammar, and language in use – and to delineate some of the conceptual and methodological issues involved. A somewhat similar theme is pursued under the aegis of the Sapir–Whorf hypothesis (*see* Sapir–Whorf Hypothesis), which concerns the influence of language on worldview. This article, however, is concerned with more subtle and fine-grained effects.

These issues have been of pressing concern to language study from at least the time of Johann Herder and Wilhelm von Humboldt. They were carried into American linguistics and anthropology in the early twentieth century by Franz Boas and then Edward Sapir. Similar concerns continued to occupy anthropology, especially cognitive and symbolic anthropology, in the second half of the twentieth century; but in linguistics, these concerns became marginalized with the ascendency of Chomskyan generative grammar. Though, to some extent, the flame was kept alight by the ethnographic wing of sociolinguistics in the work of Dell Hymes and associates (cf Bauman and Sherzer, 1974; Gumperz and Hymes, 1986). In the 1980s and 1990s, however, the dominance of generative grammar began to wane, leading to what one commentator dubbed 'the greening of linguistics,' with renewed interest in pragmatics, functionalism, anthropological linguistics, and cross-cultural semantics (cf Foley, 1997; Goddard, 1998). In a parallel development, mainstream psychology became more interested in ethnopsychology and in the new field of cultural psychology (Shweder, 1990; Shweder and Sullivan, 1993). These developments set the stage for a revitalization of studies into the interconnections between language, culture, and society.

A complex of methodological problems connected with cross-cultural semantic analysis confronts this emergent interdisciplinary field. How can one ensure that any set of semantic descriptors is not biased by the language from which it is drawn? How to achieve the maximum resolution of complex meanings? How can the process of semantic analysis be freed from subjectivity and vagueness? According to the most well-developed model of cross-cultural semantic analysis, the 'natural semantic metalanguage' (NSM) approach, the most promising solution to these problems depends on identifying a viable set of universal semantic primes (or primitives), i.e., simple concepts that have linguistic exponents (as words or wordlike elements) in all languages (cf Wierzbicka, 1996; Goddard and Wierzbicka, 1994, 2002). Cross-linguistic research indicates the existence of at least 60 semantic primes, including (using English exponents) I, YOU, SOMEONE, SOMETHING, PEOPLE, DO, HAPPEN, SAY, THINK, KNOW, WANT, GOOD, BAD, BIG, SMALL, THIS, ONE, TWO, OTHER, THE SAME, WHEN/TIME, WHERE/PLACE, BECAUSE, IF, CAN, NOT, LIKE. This restricted and universal vocabulary of simple meanings can be used as a kind of 'semantic bridge' in terms of which to articulate complex language- and culture-specific meanings in maximum detail. Because it is grounded in simple words of ordinary language, this approach makes hypotheses about subtleties of meaning accessible to the intuitions and judgments of native speakers, thus improving the verifiability of the analyses. The NSM approach is not universally accepted, however, and much valuable work in cross-cultural semantics is still conducted in essentially informal terms.

Words and Phraseology

Even between genetically related languages spoken by the people of relatively similar cultures (such as the languages of Europe), there are sizable semantic differences in all aspects of the lexicon. Sapir (1949) was thus right when he said,

"vocabulary is a very sensitive index of the culture of a people." Most people have no difficulty in accepting the culture-specific nature of words for items of material culture and for social institutions, but many find it hard to accept the extent of cross-linguistic differences in terms for value concepts, emotions, speech acts, and social categories, to mention only a few examples.

Often it is possible to nominate certain highly salient and deeply culture-laden words in a language as 'key words' of that culture, i.e., words whose meanings can provide a key to understanding whole domains of cultural attitudes, values, and behaviors (Williams, 1976; Wierzbicka, 1997). For example, it can be argued that among terms for value concepts, English *freedom*, Japanese *wa* 'harmony,' and Malay *kesetiaan* 'loyalty,' 'faithfulness' have key word status. Among ethnopsychological concepts, the same can be argued for English *mind*, Malay *hati* 'heart,' and Russian *duša* 'soul.' Single-word glosses are never adequate, however, and a reasonable understanding of the key words of any culture requires dedicated and disciplined semantic investigation. Cultures vary across time, as well as across space; so, a close analysis of meaning shifts can be revealing of sociohistorical change. For example, it can be shown that the English word *friend* has weakened considerably in meaning since Shakespeare's time, when it designated an exceptional, intimate, and life-long bond of trust, affection, and mutual assistance. This shift can be seen as linked with a shift toward more flexible and broadly based (if 'shallower') mode of social relationships.

Languages differ not only in their inventories of culture-specific words, but also in the number of words they have for speaking about a particular domain of meaning. A relatively high number of words in a single domain (lexical elaboration) are often reflective of sociocultural facts. For example, compared with most indigenous cultures, European languages have a very large stock of expressions to do with measuring and reckoning time (words such as *clock*, *calendar*, *date*, *second*, *minute*, *hour*, *week*, *Monday*, *Tuesday*, etc., *January*, *February*, etc.). At the same time, there are linguistic universals of time, such as WHEN, AFTER, and BEFORE (cf Keesing, 1994).

Two further ways in which vocabulary and phraseology can reflect sociocultural facts concern the innovation of new words and the borrowing of words from other languages. In general, new words and phrases are indexes of social change; for example, the expressions *housemate* and *online* reflect social and technological developments of mainstream English-speaking culture of the late twentieth century. Linguistic borrowings index the extent and mode of cultural influence, as witness, for example, the massive borrowing of Chinese words into Japanese, of Latin and Greek words into English, or Sanskrit and Arabic words into Malay. Some scholars argue that permeability to such a borrowing is itself an index of the social openness of a community.

Grammar

Proponents of linguistic relativity argue that in as much as speaking a language obliges individuals to continually attend to particular semantic and conceptual distinctions, this must to some extent 'shape' the habitual thinking of its speakers. Approaching the issue this way means focusing on obligatory grammatical rules and processes. On the other hand, it can be argued that optional choices in grammar, i.e., aspects over which speakers may exercise some choice and control, are more likely to reflect subtle sociocultural meanings. A familiar example is the contrast between the so-called 'intimate' and 'formal' second-person pronouns in European languages, such as French *tu* versus *vous*. Much more extensive is the honorific system of Japanese, whereby verbs carry suffixes which indicate degrees of respect felt by the speaker in relation to the individuals being spoken about. In Slavic languages, systems of expressive derivation reflect the central place of warmth and affection in Slavic cultures; in Polish, for example, a personal name like *Maria* can have as many as 10 different derivatives (*Marysia*, *Marysieńka*, *Maryśka*, *Marysiuchna*, and so on), each reflecting a slightly different emotional attitude and mood. It will be useful to look in some detail at two more examples, from Russian and English.

'Fatalism' in Russian Grammar

The Russian language has a large family of impersonal dative-infinitive constructions, which refer to inexplicable things that happen to people against their will or irrespective of their will (Wierzbicka, 1992). For example, the sentence *Ne budet tebe pasporta* meaning 'There will be no passport for you' involves a dative pronoun, a negated existential verb, and a noun in the genitive case. The sentence conveys a subtle message, not fully evident in the English translation. Essentially, a construction of this kind rules out the possibility of someone being able to obtain something beneficial and desired, implying at the same time that this is due to the fact that someone in a superior position does not want it to happen.

Another construction combines negation, an infinitive verb, and a human noun in the dative case, for example, *Ne vidat' tebe ètix podarkov* meaning 'You will never see those presents.' This construction is not so common in everyday speech, but is highly characteristic of Russian folk literature and folk speech: *byliny* (folk epic), *plač* (lamentation), in folk song, proverbs, and sayings. It conveys the impression that a desired outcome can never eventuate due to some elusive and mysterious force or power that is, so to speak, 'above' humanity.

A third construction combines a human noun in dative case with a mental verb in the 3sg reflexive form, for example, *Segodnja mne vspomnilas' Praga-sady* meaning 'Today I was reminded of Prague, of its gardens.' This depicts a mental event simply happening inside a person inexplicably, and, in a sense, irresistibly. The most important Russian expression of this sort is the ubiquitous *xočetsja* lit. 'It wants itself to me,' which suggests a spontaneous and involuntary desire. In some ways, this parallels English constructions like *It occurred to me*… or *It seemed to me*…, but whereas the pattern has a limited scope in English, in Russian it is both fully productive and extremely common.

In these and other constructions, Russian furnishes an excellent example of the grammatical realization of a semantic theme; in this case, the theme of *sud'ba* ('fate'), of not being in

control, of living in a world which is unknowable and which cannot be rationally controlled.

Personal Autonomy and the English Wh-Imperative

Compared with many languages and cultures, English makes only scant use of its imperative construction, e.g., a simple *Do this*!, whose core meaning is 'I want you to do this.' Much more frequent is the use of one of a brace of more elaborate locutions (the so-called wh-imperatives), such as *Will you do this? Would you do this? Could you do this? Would you mind doing this?* and so on. These constructions can be seen as hybrids: in form they are questions, but since they convey the speaker's wish that the addressee do something, they have a similar function to imperatives.

It can be argued that the English wh-imperatives represent a linguistic reflection of the importance, in Anglo culture, of a cultural principle that can be labeled 'personal autonomy.' Roughly speaking, this calls upon people to respect the right of other people to make their own decisions about what they will and will not do. To use a bare on-the-record imperative could be seen to infringe this principle, hence the potentially confronting message that 'I want you to do something' is embedded into a more complex configuration, which acknowledges the addressees' autonomy by inviting them to say whether or not they will comply. In form, at least the addressee is presented with the option of refusing.

Similar examples of grammatical elaboration being driven or motivated by culture-specific pragmatics or cultural values could be given from many languages and cultures (cf Enfield, 2004). Often such phenomena arise from the routinization of particular culture-specific patterns of usage.

Language in Use

Discourse Particles and Interjections

These elements exist in the border zone between grammar and discourse. While they are usually not obligatory from a strictly grammatical point of view, they are often an essential part of native-like fluency. Interjections stand as independent utterances, whereas discourse particles are integrated into the syntax of a larger utterance; but both express a speaker's here-and-now feelings, thoughts, wants, and reactions to what is happening or to what is being said. When their semantics are examined in close detail, both types of element tend to be highly indicative of sociocultural priorities, values, and attitudes.

The very common Japanese particle *-ne*, for example, conveys the message 'I think you would say the same,' consistent with the Japanese cultural value placed on harmony and consensus-seeking. English interjections and interjectional phrases such as *well* and *on the other hand* reflect the Anglo emphasis on balance and tolerance of opposing views. A multiplicity of Polish discourse particles (such as *ależ*, *skądże*, and *przecież*) and related interjectional phrases express disagreement, exasperation, and impatience, consistent with the Polish preference for spontaneous expression of emotion and lack of any inhibition on expressions of conflict or disagreement.

Linguistic Routines

These are fixed, formulaic utterances or sequences of utterances used in standardized communicative situations, for example, greetings, partings, thanks, excuses, condolences, compliments, jokes, curses, small talk, and so on. They can range in size from a single word to lengthy interchanges, and usually occur very frequently. The overall meaning of a routine cannot be 'read off' from the literal meaning of the individual words involved, e.g., *How do you do?* is not a question about health.

In general, routines are highly culture-specific both in form and in the way they relate to the sociocultural context. To illustrate, one can compare some fixed expressions in English and Ewe (Ghana and Togo, West Africa). In many societies, when one realizes that something good has happened to another person, it is usual to say something expressing one's own good feelings at the news. For example, in English one might say *Congratulations!* or *Well done!*; both expressions imply that the addressee is responsible to some extent for the happy event. In Ewe, on the other hand, appropriate things to say refer to *Máwú* 'God,' *tạgbéwó* 'ancestors,' or *ŋú-wò núwó* 'beings,' expressing messages such as 'God is strong,' 'Ancestors are strong,' or 'Beings around you have worked.' Although one function is to register and display one's happiness at the good event, the Ewe formulae are not focused on the individuals concerned. This reflects the religious belief system, which holds that everything that happens is ultimately the work of *Máwú* who may work in diverse ways through the ancestors or other spirits and divinities.

Speech Genres

Bakhtin (1986) defined speech genres as 'relatively stable and normative forms of the utterance' into which we 'pour' our everyday speech. The concept is a very broad one, subsuming examples that differ in size and complexity as widely as (to illustrate from English) *joke*, *toast*, *speech*, *letter*, *eulogy*, *submission*, and *lecture*. Bakhtin stressed that the repertoire of genres available to a speech community changes according to historical and sociocultural conditions.

This conveniently can be illustrated with the (now passé) Polish 'microgenre' of the *kawał* (plural *kawały*) which, roughly speaking, was a kind of conspiratorial joke. Most *kawały* were political, expressing national solidarity vis-à-vis foreign powers, which have been so much a part of the Polish historical experience: the foreign partitioning powers in the nineteenth century, the Nazi occupation during World War II, the Soviet-imposed communist regime in postwar Poland. *Kawały* circulated widely, the anonymous creations of an oral culture. Like English *jokes*, they were intended to promote pleasant togetherness, i.e., to make the speaker and the addressee feel good together, but one did not value a *kawał* for its ingenuity, novelty, or sophistication (as one did, and does, *dowcipy* 'witty jokes'). More important was the feeling it gave of belonging to an in-group, the implication being 'I can say this to you, but there are some people I could not say this to.' For example, in 1981 after martial law had been imposed in an effort to suppress the Solidarity movement, every new demonstration, strike, or protest was ascribed to 'Solidarity extremists.' A *kawał* from that time gave examples from a 'TV

Dictionary' as follows: 'two Poles – an illegal gathering; three Poles – an illegal demonstration; 10 million Poles – a handful of extremists.' Clearly, though the Polish genre *kawał* may overlap in some respects with the English genre of a *joke*, it is not identical with its nearest English counterpart. Equally clearly, the precise nature of the Polish genre was a response to (and an index of) social conditions of Poland.

Speech Styles

Speech styles represent specialized 'ways of speaking,' that are recognized (and, usually, named) by the speech community as appropriate for use with certain categories of interlocutors or in certain situations. When examined in detail, both the stylistic conventions and social parameters of the speech styles can show much about sociocultural conditions. One common pattern can be illustrated from Yankunytjatjara (Central Australia), which has a special indirect speech style *tjalpawangkanyi* (*wangkanyi* 'talk') for use with people whose kin relationships call for constrained behavior, and a boisterous joking or teasing style (*inkatjingani*) for use with people whose kin relationships imply mutual acceptance and a lack of any power relationships (Goddard and Wierzbicka, 1997). *Tjalpawangkanyi* has a distinctive vocal delivery (softer, slower, higher pitch) and an exaggerated rising intonation, as if to give the impression that the speaker is merely musing aloud. Direct references to the addressee, including imperatives and vocatives, are carefully avoided. Overt expressions of denial, refusal, or disagreement are also scrupulously avoided. There is liberal use of discourse particles and interjections that express uncertainty, hesitation, and minimization. Another striking feature, reported also of respectful speech styles in many other places, is generality of reference. Speakers avoid using any expression which unambiguously indicates a person, place, or thing, preferring vague locutions like 'that one (person)' and 'around here.'

The social meaning of *tjalpawangkanyi* refers to the Yankunytjatjara social emotion *kunta*. Usually glossed as 'shame,' 'embarrassment,' or 'respect,' this involves a sense of social difference and discomfort in the other person's presence, and the desire to avoid doing anything which might cause the other person to think anything bad about one. The strongest *kunta* is evoked by the respectful *umari* ('avoidance') relationship between a man and his parents-in-law, which absolutely prohibits personal contact of any kind. Less-severe *kunta* is felt in the presence of the siblings or cousins of *umari*, and in other relationships where propriety is important, the very relationships for which *tjalpawangkanyi* is appropriate. In this culture, then, the indirect speech style can be seen both as a kind of partial avoidance and a way of giving voice to *kunta*. In other societies, indirect speech styles can serve quite different purposes.

Yankunytjatjara joking styles are at the other end of the spectrum to *tjalpawangkanyi*. They bend, flaunt, or even parody the normal conventions of interaction. All the linguistic forms excluded from *tjalpawangkanyi*, including imperatives, vocatives, contradiction, exclamations, and sensitive vocabulary items, flourish in this style. Participants delight in banter, mock insult, and make the most of any chance to defy, challenge, or demean each other. Sometimes there will be sexual innuendo and risqué comments that consciously play on kin-role expectations. In extreme versions, such banter becomes blatantly obscene. Joking, uninhibited speech styles are reported from many societies around the world. Although at a general level one can say that he or she expresses 'solidarity,' 'intimacy,' or the like, the rich social meanings involved cannot really be summed up in a few words, and detailed study reveals subtle but important differences.

Discourse Styles

At an even broader level, entire speech communities can be characterized as having certain tacitly shared understandings about how it is appropriate to speak in particular, culturally construed situations. In some societies it is normal for conversations to be loud, animated, and bristling with disagreement, while in others people prefer to avoid contention, to speak in well-considered phrases, and guard against exposure of their inner selves. In some societies, silence is felt to be awkward, while in others it is welcomed. In some societies, it is considered very bad to speak when another person is talking, while in others this is an expected part of a co-conversationalist's work (Tannen, 1981). Researchers in the ethnography of communication and in cross-cultural pragmatics are concerned to spell out the differing norms, values, and attitudes (sometimes called cultural scripts), which underlie and explain these behavioral differences (Saville-Troike, 1989).

Cultural norms about expressing emotions (what one feels) vary widely. For example, in mainstream Anglo societies, the expression of negative feelings is relatively constrained (cf 'cheerful' English routines such as *How are you? I am fine*). In Russian and Polish societies, by contrast, a greater value is placed on the immediate and spontaneous expression of emotions, 'bad feelings' as well as good ones. In yet other societies (for example, in Malay and Japanese societies), the cultural ideal is to maintain a calm equanimity of expression, moderating the expression of good feelings as well as bad ones. These differences are reflected also in facial expressions and other aspects of nonverbal communication. Needless to say, these characterizations are only approximate. Many modulations and variations are found across cultures.

Even within a single language group, there can be significant differences. For example, it can be argued that contemporary Anglo-American culture has developed some distinctive routines and expressions for expressing enthusiasm, optimism, and a 'positive attitude': *Wow! Great! How nice! That's fantastic! I had a terrific time! It was wonderful! Have a nice day!* Sociological studies of cultural attitudes toward emotions have also shown that Americans place an exceptional emphasis on enthusiasm.

Along with differences in emotional expression, other broad parameters of social variation in discourse style concern the expression of conflict or opposition between interlocutors' views (what one thinks) or wishes (what one wants). Japanese society, for example, is a society in which overt expression of differences and disagreements is discouraged, on account of the prevailing cultural value of *wa* (roughly, 'harmony'). For example, a well-known article by a Japanese author (Ueda, 1974) is titled *Sixteen Ways to Avoid Saying 'No' in Japanese*. In Jewish culture (Schiffrin, 1984; Blum-Kulka, 1982), on the

other hand, an overt and intense clash of views and evaluations is not only considered nonthreatening, but is often actively welcomed.

Differences like these not only contribute powerfully to the texture of everyday social interaction and to the character of interpersonal relationships, but also, arguably, exert an influence, through socialization, on the formation of personality types.

Editor's Note

A widely-cited and current text in Language and Society is Martin Montgomery (2013). Goddard and Wierzbicka's entry assures us that any language is inseparable from "the social, cultural and historical experience of its speakers." The language of conflict in the Middle East is a current case in point and an explicit theme in the work of the Palestinian linguist Yasir Suleiman. See his A War of Words: Language and Conflict in the Middle East (Cambridge University Press, 2004) or his 2013 book, Arabic in the Fray: Language Ideology and Cultural Politic (Edinburgh University Press). The leading journal in this field is Language in Society, published by Cambridge University Press and currently in its 43rd volume; all of the most frequently cited papers in this area are published there. Recent work in the area has focused on language and globalization; multilingualism; and language, social policy, and ideology. Examples of current work in these areas of research would include: Nikolas Coupland (2011), Ingrid Piller and Jinhyun Cho (2013), and Michal Krzyzanowski and Ruth Wodak (2011).

Language and Thought: The Neo-Whorfian Hypothesis

Antoni Gomila, Campus Carretera Valldemossa, Palma de Mallorca, Spain

This article is a revision of the previous edition article by E. Hunt, volume 12, pp. 8310–8315, © 2001, Elsevier Ltd.

Abstract

During the last decade, a renewed interest in linguistic relativism has given rise to an exponentially growing body of literature concerning the influence of language on cognition. The current concern is not whether language influences cognition, but rather how much, and to what extent. After briefly characterizing Whorf's linguistic relativism, the current neo-Whorfian hypothesis is introduced, and a selection of the most relevant and influential studies is reviewed. The conclusion contends that the influence of language on cognition is not homogeneous, but depends on how much recoding is brought about during linguistic development.

Linguistic relativism finds its roots in Romanticism: in the reaction to the supremacist attitudes of the Enlightment thinkers, who were in the business of establishing hierarchies of languages in order to find the 'perfect' one (generally, French). Romantic thinkers, such as Herder, viewed peoples ('Volks') as incommensurable historical entities, whose worldviews are somehow condensed in their respective languages. In other words, language was viewed as the accumulated wisdom and repository of experience of a particular People.

This Romantic attitude found its proper place in the development of Anthropology as a science in the late nineteenth century. A privileged area of research in this regard was the documentation of the Amerindian languages as their speakers were being exterminated. This work naturally gave rise to the linguistic relativism hypothesis: what one can think is constrained or molded by the language one speaks. Whorf's originality (1956), in this regard, lies in his particular way of arguing for this view and in his effort to provide evidence for it, instead of taking it as an obvious postulate.

Whorf's reasoning sides with the functionalist American tradition. Following William James' views, Whorf describes the infant development as the process of making sense of the 'booming, buzzing' confusion of early sensory experience. Language provides a set of 'ready-made' categories. By learning a language, then, we acquire a categorical system that allows us to make sense of our experience. If different languages 'carve nature at different joints,' speakers of different languages will come to experience the world differently. To put the point in antirealist terms, as sometimes Whorf did, they will come to experience different worlds. Language, from this point of view, is not just a communicative tool but also a representational one.

This simplistic argument is not coherent, though: it does not apply to language the general point about sensory confusion. Language is thought to provide a way to structure one's experience, as if it were a salient part of one's experience in the first place, as if the sounds of language were not part of that initial confusion. In addition, there could be categories common to all languages. In other words, Whorf's relativistic hypothesis is grounded in taken-for-granted assumptions.

It is also true that Whorf suggests in some passages that thought is carried out in the particular language one speaks: "Thought takes place in a language, be it English, Sanskrit or Chinese" (Whorf, 1956: p. 283). But this is not a core aspect of linguistic relativism as such. The latter just requires that what can be thought is configured by the categories of one's language, that one's global conceptualization of experience derives exclusively from one's linguistic experience: the doctrine of linguistic determinism.

The contemporary neo-Whorfian versions of linguistic relativism (Lucy, 1992; Gumpertz and Levinson, 1996; Levinson, 2003; Casasanto and Boroditsky, 2008) avoid the epistemological and metaphysical assumptions of Whorf, and are not committed to the contention that thinking takes place in a natural language. The focus is on the central argument for linguistic relativism, which can be summarized this way:

Premise 1: Linguistic diversity: languages differ in their lexical and morphosyntactic rules and categories.

Premise 2: Linguistic determinism: the linguistic ways of categorizing human experience determine the cognitive ways of categorizing it.

Conclusion: The categorical structure of thought varies according to the language of the thinker.

Notice that this is more a deductive schema than a well-specified hypothesis. All sentences in this reasoning admit of different degrees of modal strength, while for any of them some sort of linguistic relativism follows. Thus, linguistic diversity may be underlined (Levinson, 2003) or downplayed, for instance, as parametric variation of linguistic universals (Chomsky, 2007). In the same vein, the second premise affords a strong reading (all cognitive categories are linguistic) or a weak one (at least some cognitive categories depend upon the language acquired) (Kay and Kempton, 1984). Understood this way, Whorf provides a concrete program of empirical research, to find out whether, and to what extent, it is true that linguistic structure influences cognition: select a way in which languages differ, and see whether speakers of those languages differ in some nonspecifically linguistic cognitive task (perception, memory); then, pay attention to how such cognitive abilities appear in ontogeny, to confirm whether differences appear only due to language mastering. Such a program has given rise in the last decade to a lively neo-Whorfian program in contemporary cognitive science, whose main contributions are novel paradigms, rigorous experimental control, and piecemeal examination.

In what follows, I will select the most outstanding recent contributions in this area. Then, I will discuss which conclusion is best supported by the evidence – the influence of language on cognition not being into question, but rather how much influence it has, in which areas, and by which mechanism. The conclusion will turn out to be that relativist influences do not happen across the whole cognitive system, but just in late-developing, more abstract, cognitive domains. They might also show up, though, in early-learned perceptual categories, as long as they involve recoding of sensory experience. There is no need for radical constructivist assumptions ('no perception without language') to accept Whorfian effects: they may just involve overcoming initial implicit preferences, which are not linguistically coded, and making some perceptual aspects more salient because of the way language drives attention to them, as cognitive development benefits from the abstract recoding fostered by lexical development (Gomila, 2012).

Color Terms Influence Color Perception and Memory

The Basic Color Terms of Berlin and Kay (1969) made a long-lasting impact by challenging the relativistic hypothesis. They claimed that color perception is independent of the color terms of one's language, and also, they downplayed linguistic diversity, claiming that languages differ in their color vocabularies in a systematic way. The outcome of the debate that followed was not a rejection of the notion of basic color terms, but rather a heightened awareness of the need to be more careful in experimental research in two directions: in introducing greater experimental control when looking for nonverbal cognitive effects of such different vocabularies; and in carrying out an ambitious world survey of color vocabularies, in order to assess the claim of a universal pattern of increasing differentiation of colors, the World Color Survey (Kay and Regier, 2003), which is made available through the online World Atlas of Language Structures (Kay and Maffi, 2011). It was realized, though, that linguistic diversity is an independent issue: linguistic differences may have a cognitive effect, even if these differences are not arbitrary or purely conventional.

A great deal of effort focused on color discrimination tasks to assess whether the categorical effect – the fact that discrimination is easier between category than within category – in color perception is sensitive to linguistic differences in establishing categorical borders. Thus, Kay and Kempton (1984) supported the role of linguistic categorization in perception through different categorical perception effects across languages. In Tarahumara, a Mexican indigenous language, there is just one term for the part of the spectrum that we divide between blue and green. Kay and Kempton reasoned that if language influences cognition, speakers of English would distinguish more strongly between color samples that they call 'green' and 'blue' than between color samples that fall into the same color category. They posited that this would be true, even if the differences in physical terms were the same in all instances, while for speakers of Tarahumara that would not be the case. The experimental paradigm consisted in three color samples, and the participants had to decide which one was the most different. As hypothesized, the Tarahumara speakers – lacking a verbal distinction – discriminated among the examples in relation to their physical differences, while the English speakers saw the similarities and differences along their lexical categories. Kay and Kempton reasoned that this could be due to the fact that the strategy of the participants could be that of labeling the samples in the first place, calling each sample 'blue' or 'green' – a strategy not available to the Tarahumara speakers. The sample that was categorized differently from the other two would be the one chosen as most different, even if the physical differences among the different samples were the same.

To test this explanation, they devised a second experiment. To block that strategy, this time, the three color instances were not presented simultaneously, but through a moving window that allowed the participants to see two of the three samples at the same time: the one on the left and the one in the center, or the one in the center and the one on the right. In each trial, the participant had to determine whether the left example was 'greener' than the one in the middle and whether the right example was more 'bluish' than the one in the middle. In order to answer which difference was the greatest: the one between the two 'greens' or the one between the two 'blues.' In so doing, the center instance was labeled both 'green' and 'blue' in the same trial, so that the discrimination could not be due to its categorization as one of the two. In this setting, the effect found in the first experiment disappeared, and speakers of English performed as the speakers of Tarahumara. Language, then, can be said to be influential in how we perceive similarities and differences.

This comparison also makes it clear that we do not perceive colors only when we have a term to denote them; it is not that without language we would not have color experiences. It is rather that language plays a role in structuring our perceptual space, particularly in memory tasks. Thus, Berinmo speakers from Papua New Guinea exhibit enhanced color discrimination from memory across Berinmo category boundaries, but not across English boundaries, while English speakers show the reverse pattern (Robertson et al., 2000). In general, if two colors are the extension of the same term in a particular language, speakers of that language will judge the two colors to be more similar and will be more likely to confuse them in memory than speakers of a language with a term for each color. These differences develop early in infants and coincide with the acquisition of color terms (Roberson et al., 2004).

Further studies also confirmed the Kay and Kempton's verbal interference effect: crosslinguistic differences in similarity judgments and recognition memory can be affected by direct verbal interference. This suggests that it is language, itself, that is involved 'online' during these tasks. Verbal interference has also been shown to affect speeded color discrimination and visual search tasks across the English blue/green boundary (Drivonikou et al., 2007; Gilbert et al., 2006).

But such linguistic effects have been found not just in nonverbal memory tasks, but also in discriminative tasks. Winnaver and his colleagues have recently compared Russian and English speakers on a simple similarity judgment task, focused on the blue part of the spectrum. It turns out that in Russian two 'basic' terms (according to the Berlin and Kay definition) correspond to the English 'blue': 'golubóy' and 'siniy.' The former is typically applied to the sky, the latter to the sea. Winaver et al. (2007) showed their participants three chips

of the blue spectrum: one being the sample, and two options from which to choose the one that's more similar to the sample. They reasoned that if linguistic representations are used to deal with ambiguous color samples – as claimed by critics of relativistic effects – then no language effects should appear in this task, given that it is an objective one that participants can solve with high accuracy. Reaction times were measured as an indication of the relative easiness of the task. Finally, the task had to be carried out under two conditions: with and without verbal interference. The main hypothesis concerns the effect of the categorical boundary on Russian speakers. If color vocabulary has cognitive effects, performance of Russian speakers should differ from English speakers with regard to perceptual discrimination performance across the boundary. Additionally, verbal interference should affect only Russian speakers. Therefore, it is the cross-category trials – when the participants had to choose between a 'golubóy' item and a 'siniy' item – in which critical differences were to be expected. Russian speakers should be faster at cross-category trials than within-category trials, whereas no difference is expected by English speakers. The results nicely confirmed the predictions: Russian speakers were faster at judging similarity cross-categorially than within-categorially, and verbal interference affected more Russian cross-category than within-category judgments.

Spatial Terms Influence Nonverbal Spatial Tasks

Languages offer different kinds of terms to talk about space. Levinson (2003) has distinguished between three main areas of spatial cognition which can also be found in language: deixis, topology, and frames of reference. Deixis concerns distance from ego ('this' versus 'that') and direction ('coming' versus 'going'), and involves radial rather than vector characterizations (it is possible to 'come here' from any direction). Topological distinctions concern relations of contact, containment, or propinquity between a 'figure' object and a 'ground' landmark. Finally, the frame of reference provides a way to specify directions – taking ego as polar coordinates – and it is thus most relevant for orientation and navigation.

Bowerman studied some crosslinguistic differences in topological terms (Bowerman and Choi, 2003). Thus, for instance, Choi and Bowerman compared how English and Korean speakers differ in which spatial relationships they pay attention to. In English, the prepositions 'on,' 'in,' and 'under' specify the possible relations between an object and a container. Korean, though, lacks a similar specification, but it marks morphologically whether an object is tightly or loosely limited by another (for instance, a finger by a ring versus a picture and the wall), an aspect of the situation which English does not specify. Their comparative studies revealed that English and Korean pay different attention to these spatial relations, concluding that acquisition of spatial semantics of the terms of one's language influences children's categorization of spatial relations. This does not mean that babies learning English are blind to the tight fit versus loose fit containment relations: all babies are sensitive to this difference by 9 months of age (McDonough et al., 2003). It is rather that – given that the language they learn does not pay attention to such differences – those differences lose cognitive saliency later on. A study with deaf children, though, suggests that without linguistic input, some spatial relationships take much longer to be understood (Gentner et al., 2013).

As regards frames of reference, three different lexical systems have been distinguished (Levinson, 2003):

1. Object-centric or intrinsic framework terms are terms that specify intrinsic positions of landmark objects to extract a direction (often by metaphorical projection of body parts). In English, such terms as 'heads' and 'tails' (mostly for coins, but extensible to other objects), 'front' and 'back,' or 'top' and 'bottom' specify a particular part of a landmark that can be used for orientation.
2. Egocentric or relative framework terms are indexical terms whose meanings require attention be paid to the position of the speaker. In English, some of the previous terms can be so used, if they specify a part of the speaker (whose corresponding direction, though, moves with the moving subject). Such terms as 'in front of,' 'to the right of,' or 'behind' are of this kind (as in 'it's in front of you,' 'the seat to my right,' or 'put it behind the table').
3. Allocentric or absolute framework terms are terms that specify absolute positions in space. In English, terms such as north or south are of this kind (as in 'travel North' or 'it's more to the South').

Most languages combine two or more of these systems. While in English allocentric spatial terms seem to be exceptional, they seem to be the rule in languages such as Tzeltal (a Mayan language); some Australian aboriginal languages, such as Guugu Yimithirr and Kuuk Thaayorre; and some Asian languages, such as rural Tamil, Longgu, and Arrernte (Levinson and Wilkins, 2006, which is a survey of linguistic diversity in space and movement description). Notice that such absolute directions are more arbitrary and abstract than intrinsic or relative terms, since they cannot be directly perceived; they do not depend upon endpoints or milestones, and orientation requires constant tracking of one's position in a fixed spatial map.

Brown and Levinson (2009) have studied the Tzeltal linguistic community of Tenejapa. The Tzeltal spatial vocabulary lacks terms corresponding to 'left' and 'right,' but has words corresponding to absolute positions, formed by abstracting from the slope of their land. In this case, absolute position terms correspond to 'uphill' (which is South) and 'downhill' (which is North), so that they say things like: 'Give me the uphill glass,' or 'the rope is downhillwards the bottle,' regardless of current position of the speaker. For orientations corresponding to East and West, the term is the same, corresponding to 'across.' Tenejapan people are oriented by reference to this framework at all times, while they can also use an intrinsic system of reference, with terms that refer to body parts. The question is whether this preference for an independent frame of reference plays a cognitive influence beyond language.

According to Levinson and Brown, the answer is yes: speakers of 'allocentric' languages differ from speakers of 'egocentric' languages in nonverbal tasks of spatial reasoning, of visual memory, and of gesture. The differences occur in forms related to their different lexical systems, thus providing

evidence for a role of language in cognition. Levinson and Brown set several different nonverbal spatial tasks for speakers of these languages, and compared their performance to that of speakers of 'intrinsic' and 'egocentric' languages (such as Dutch). Tasks required memory of spatial configuration, motion, and path direction. Thus, in a spatial reversal task, Tzeltal speakers saw the spatial ordering of four items on a table, for instance, and were asked to remember the spatial ordering of three of them. They had to reconstruct that 'same' ordering on another table, which they approached from the opposite side (a 180° turn). The Mayan put the objects in the same allocentric ordering as the original set (what was to the left was again to the left, despite the subject reversal), while Dutch control participants would go for the same egocentric ordering (what was to the left was now to the right). Similarly, in a spatial-reasoning task, participants were observed to find out whether they preferred a transitive ordering of objects in terms of a left to right (egocentric) or a north to south (allocentric) frame of reference. Again, the Dutch used the egocentric and the Tenejapans used the allocentric framework.

Notice that the strategy consists in presenting an ambiguous task, which is why it was described as the 'same,' as opposed to the same. The instructions could be understood both ways. Therefore, the evidence does not show that any of the participants could not solve the task the other way. In fact, further research showed that both groups could solve the task both ways (Li et al., 2005). The results, though, do show a different preferential understanding of the task, related to the dominant spatial vocabulary.

Numerals Are Required for Counting

Numbers, or rather, numerals, have been another outstanding area of research. Numbers are abstract entities, which cannot be grasped directly, but through a symbolic means of representation. Numerals are the terms language offers to denote numbers; for arithmetics, other, more specific symbols may be required (functions, operations), in addition to a graphical numerical representation. Languages also differ in their numeral systems, so the question arises: to what extent do these differences matter for arithmetic competence?

There is a broad consensus that some numerical concepts are independent of language. There is evidence that we share some basic notions with animals, such as 'more or less' and 'numerosity,' given that prelinguistic infants and some nonhuman animals can discriminate the numerosity of small groups of objects and can recognize that one is larger or smaller than another (Starkey et al., 1990).

However, when it comes to exact numerical concepts larger than four, it is clear that they are acquired through language. It is a prominent example of the concepts that depend on language, at least at two levels: developmentally, in that the term comes first and then the child has to somehow come to understand its meaning; and processually, given the evidence that their linguistic representation is involved in calculations and arithmetic tasks (Spelke and Tsivkin, 2001). The authors of this study found that bilingual subjects trained on new number facts in one language, recalled those facts faster and more reliably when tested in that language, than when tested in their other language.

As with color, though, languages may vary a lot in their numbering systems. Some languages may have a very short numeral repertoire, as in 'one-two-many,' while others avail themselves a generative system that guarantees a numeral for each possible number, such as that found in Western languages. Peter Gordon has focused on one of the 'one-two-many' languages: the Pirahä, an Amazonian language spoken by a tribe of hunter-gatherers (Gordon, 2004). The question is whether Pirahä speakers – having terms just for one, two, and many – are somehow impaired in arithmetic functions, such as counting, addition, or subtraction. According to Gordon, they are unable reliably to tell the difference between four and five objects placed in a row. In other words, Pirahä speakers perform like nonverbal infants and nonenculturated primates, lacking a symbolic means for counting. The procedure Gordon used was a sort of imitation game: he laid out a random number of familiar objects, like sticks and nuts, in a row, and the participant (there were seven of them), was supposed to do the same. For one, two, and three objects, the Pirahäs' row matched Gordon's sample. But when the number of objects was from 4 to 10, Pirahäs just approximated the number, with increasing deviation as the row grew longer. In another task, participants were shown several boxes, with different quantities of fishes depicted on top. Seconds later, they failed to take this difference into account in order to remember which box kept a hidden object. Similarly, for rhythmic tapping they could imitate tapping on the floor of up to three taps, they failed to mimic strings of four or five taps. Gordon observes that the Pirahä do not need to count in daily life, and concludes that this evidence demonstrates that numerical concepts beyond three are acquired through the acquisition of the corresponding numerals.

Similar results were obtained by Pierre Pica with speakers of Mundurukú (Pica et al., 2004), another Amazonian language which lacks numerals beyond 5, even though Pica and collaborators avoid a relativistic conclusion. While speakers of Mundurukú are able to compare and add large approximate numbers beyond 5, they fail exact arithmetic with numbers over 4 or 5. Again, this evidence is interpreted in terms of a dual system of numerical competence: a basic nonverbal system of number approximation, and a language-based counting system of exact number and arithmetic. However, it again remains to be established what the precise role language plays in the understanding of numbers. This must be determined in order to know if the language-based system is not a real improvement on numerical cognition (as Pica thinks), or if abstract understanding of concepts as language-dependent is a relativist effect (as Gordon affirms). The question is as follows: which relationship holds between the two systems, once the recursive number system made possible by numerals is in place? Is it a complementary one? Or is it rather a transformative one, given that exact number understanding opens up a whole new world of cognitive possibilities? At least part of the answer to this latter question will depend on how number understanding is developed. In other words, what does it take to grasp a recursive, potentially infinite system, like the number one?

A way to address this question can be found in Pica's observation that numeral expressions in Mundurukú are long,

often having as many syllables as their corresponding quantity. The words for three and four are polymorphemic: 'ebapug' means 'your two arms plus one,' and 'eba-dipdip' means 'your two arms plus one plus one.' This suggests the rudiment of a way to name quantities in a systematic way, by establishing a correspondence between quantity and syllabic structure. Whereas it is not a feasible procedure in general, it makes clear that counting is the required ability to master. Pica suggests that other languages of the Mundurukú family use a base-2 system of numerals – in which the corresponding terms of 'eba' get repeated – but even in that case, the most revelatory aspect is that it suggests a basic form of counting that is related to body parts. Similarly, the expression for 5 corresponds to 'a hand' or a 'handful.'

This required emphasis on counting as the key ability to go from numerosity and approximate quantity to exact number prompts us to refer in this context to Saxe's (1982) study of Oksapmin, as a sort of middle, transitional case. Oksapmin is a Papua New Guinea linguistic community, which at the time of study was undergoing a cultural change related to the introduction of money. This made counting practices more relevant, and required an amplification of the numeric system to deal with the new arithmetic operations involved in the use of money. According to Saxe, the traditional Oksapmin number system for counting is also finite and based on the body, but this time 27 consecutive numerals are available. As a matter of fact, the terms constitute an order sequence of body parts, starting with the thumb on one hand, and proceeding through the upper periphery of the body and then down to the other side. No other symbolic representation is available: number 14 corresponds to the nose, and the forearm is 7. This numeric system was used for counting and measuring. However, it was not put to traditional arithmetic use, and no term exists for mathematical concepts of division, or for rational and irrational numbers.

During the 1970s, money was introduced to the Oksapmin community, through paid work and commerce. This created a denomination problem, given the shortness of the numerical system. The adaptation that took place to deal with the new social need for referring to currency was a base-20 system, that recursively uses the basic terms in successive cycles, as required. Such a change went hand in hand with a reorganization of arithmetic thought: beginning with the new coin counting practices in commerce, for instance, arithmetic functions – such as addition and subtraction – later emerged. The culmination was the emergence of mental calculus – the ability to count without physical support (fingers in our case; upper body parts in the Oksapmin's case). Saxe (1982) found evidence of this cognitive transformation in the making, by comparing four groups of subjects with respect to addition and subtraction problems. The groups included men who had owned a trade store for at least 2 years; men who had returned from a period of work at a plantation but did not own a trade store; young adults who had not been to a plantation, and, therefore, had no money experience; and older adults who had only a cursory level of experience with the money economy. He could witness the process by which practice with money pushes for a recursive open-ended numerical system that is increasingly used for mental calculation. Addition problems were solved in that way by the most experienced subjects. A procedure of starting with the first figure and then following the bodily series for the other figure was used by less experienced subjects. This followed more simple strategies – like the double enumeration one – in which each figure, which corresponds to a numeral-body part, is mapped onto the corresponding body part to begin with, and then a procedure for establishing correspondence is tried. In general, while all groups could do addition with coins, subtraction with coins was difficult for the groups not habituated to money. Without coins, performance of all groups differed in proficiency, in a rank that went from nonceiling competence for experienced traders, to null for nonexperienced older adults. Nonexperienced adults, though, performed at a higher than chance level, an indication of a greater facility for learning.

In summary, Oksapmin exemplifies the central idea of the 'conceptual metaphor' theory: that understanding of abstract concepts is achieved in terms of more concrete ones. Most importantly, these concrete ones are 'image schemas' and spatial egocentric concepts based on the body (Núñez, 2008). While these basic schemas are thought to be primitive, there are many of them. Languages freely choose from this pool of conceptual resources in a rather arbitrary manner, which, however, has strong cognitive effects. In other words, numerals do not create number understanding out of nothing. When numerals are encountered by children in their process of language acquisition, they make sense of them in terms of one of the basic body schemas available that the group is already using to make sense of numbers. In this way, such schemas scaffold the individual cognitive development. Numerical problems can only be dealt with to a certain extent in such a system. Purely mental processes result from internalization of such practices, which also limits the scope of tractable arithmetic problems. Change in these systems is also possible by standard processes of cultural innovation, but what is kept constant is the bodily grounding of conceptual understanding.

Linguistic Differences in Temporal Concepts

As observed by Whorf, languages differ in terms of the time units they distinguish. As important as that is, languages also differ in the different aspects of time they require a speaker to morphologically mark (e.g., tense, aspect, and mode), and in terms of the means for temporal deixis they make available (e.g., now, tomorrow, and later). Moreover, most temporal concepts – just like abstract mathematical notions – are grounded in spatial metaphors (which entail different frames of reference), and languages also differ in which conceptual metaphors they use (Casasanto and Boroditsky, 2008).

For example, Boroditsky studied whether the preference for absolute spatial orientation also influenced these other cognitive areas (Boroditsky and Gaby, 2010). She gave participants a set of pictures showing some kind of temporal process (like an aging man or a growing crocodile) and asked them to arrange the pictures according to temporal order. They tested the participants in two separate places, differently positioned according to cardinal orientation. Previous studies had shown that time direction in English and Hebrew speakers is

conceived in terms of writing direction: left to right for English, right to left for Hebrews (Fuhrman and Boroditsky, 2010). Given that speakers of Kuuk-Thaayorre lack terms for left and right, they did not arrange cards from left to right, more often than from right to left. The pattern of their responses was rather east to west orientation (metaphorically grounded in the daily process of the sun): if they were placed facing South, they placed the cards left to right, but if they were placed facing North, they placed the cards right to left. Thus, speakers of Kuuk Thaayorre exhibit a greater navigational ability and spatial knowledge than speakers of languages with relative frames of reference. They keep track of where they are, even in unfamiliar landscapes or inside unfamiliar buildings, because otherwise they could not talk about space.

Many other metaphors are used in different languages: speakers of English tend to use a horizontal spatial metaphor (past is behind, future is ahead), whereas speakers of Chinese use a vertical metaphor (future is down, past is up) (Boroditsky, 2001). The demonstration that this is not just a *façon de parler*, but that it reveals how events in time are conceived is found in the example that, given a spot in space directly in front of the subject to stand for today, when asked to place a spot for yesterday and tomorrow, English speakers use a horizontal axis, while Chinese speakers use a vertical one (Boroditsky, 2007). A similar metaphorical understanding was found by Whorf in the Hopi language, which revealed a circular understanding of time.

Núñez's work on the Ayamaras' conceptual metaphors for time also deserves mention (Núñez and Sweetser, 2006). The Ayamara linguistic community is over 2 million people; they live in the Andes highlands of Bolivia, Perú, and northern Chile. They reverse the central Western spatial metaphor time: instead of the projection 'front of ego: future/back of ego: past,' they use exactly the converse one. The basic word for front, 'nayra,' is also a basic expression meaning past, whereas 'qhipa,' which is the basic word for back, also means future. Thus, for example, 'nayra mara,' which translates literally as 'front year' refers to the previous year. Again, this is not a purely linguistic difference (a sort of frozen metaphor), but it affects how Aymaras understand temporal relations. In this case, Núñez found the evidence in the deictic gestures that accompany Aymaras talk of past and future: deictic temporal reference involved pointing to one's back to refer to future events and to one's front to refer to past ones, with distance from one's self-indicating temporal distance.

Conclusion

We have just sampled the recent neo-Whorfian literature. But it is enough to find a common pattern in the evidence: language has a deep impact on cognitive development. It is not that all cognitive development is driven by language – that's too strong a position; but when linguistic coding plays a role on categorization, linguistic differences give rise to cognitive difference. These are not absolute differences, but rather force fields, that make some differences more salient and relevant.

Language exerts its influence on cognition through linguistic development. It changes the initial, sensorimotor, and imagistic medium of the mental representation of a restricted implicit system into a more powerful explicit system. Or it facilitates attention to dimensions of experience for which no initial preference is set. Lexical labeling is not just a matter of tagging a previously and independently constituted symbolic concept, but the way symbolic concepts are grasped (Lupyan, 2008). It has to be kept in mind, though, that the greater impact of language on cognition is made evident, not in comparing speakers of two languages, but in comparing verbal minds to nonverbal ones (Gomila, 2012).

This article is a revision of the previous edition article by S.G. Thomason, volume 12, pp. 8315–8319, © 2001, Elsevier Ltd.

Abstract

With examples drawn from a variety of languages but especially those found in the Balkans, this article discusses language contact from a variety of perspectives. The author first places contact between speakers of different languages in its sociolinguistic context, then briefly traces the history of the study of language contact, followed by a discussion of the mechanisms of language contact, its manifestations, and its effects.

Introduction

Although language exists in the minds of individual speakers, it is also very much a social phenomenon, involving more than one speaker engaged with another in acts of communication. Thus, speakers of a language, any language, (except, of course, those with a small number of speakers who are not in a position to talk with one another) are always interacting with other speakers. Generally, the interaction takes place between speakers of the same language, but what does 'same language' mean here? It is known that no two speakers of what is ostensibly the same language speak exactly identically, and that, moreover, the line between different languages and different dialects of the same language is often very hard to draw and is generally open both to interpretation and to external manipulation, for example, for political or nationalistic purposes.

Thus in the normal course of language use, contact between speakers of nonidentical language systems takes place again and again. Contact between speakers of different dialects is at one end of a continuum of degree of identity in such situations; at the other end is contact between speakers of different languages. Moreover, even pairs of different languages may show different degrees of similarity, when one is set in opposition to another, so that Russian and Ukrainian are in many ways more similar to each other than either is to Hindi or to Thai. Linguists usually refers to such contact situations as 'language contact' or 'dialect contact,' as the case may be, even though it must be emphasized that the contact is between speakers in concrete communicative situations and not between languages or dialects as systems in the abstract. Moreover, even where one might recognize a construct such as a 'macrolanguage' to subsume all varieties of a given speech form or in cases where there is a standard language that is the default that one thinks of when referring to 'language X,' the speaker-to-speaker contact that is generally characterized as 'language contact' actually involves a dialect, that is, the particular variety of the language, the specific dialect, that each speaker is using in that communicative encounter.

The study of language contact has a long history, inasmuch as a mixing in of words and even other linguistic elements was recognized by ancient observers; the Romans, for instance, were aware of the presence of Greek words in their Latin, and certain spelling conventions, such as the use of the letter *y*, were used at one time by Romans writing Latin to mark words of Greek origin. And, as a true science of language emerged in the West in the nineteenth century, through the determination of the history of various classical languages of Europe, especially Latin and Greek, and their genealogical – a term often used now instead of the more traditional 'genetic,' because of the unwanted biological implications of the traditional term – relationship to other languages in Europe, such as Gothic and Irish, and in Asia, such as Old Persian and Sanskrit, the distinction between 'inherited' forms and structures, i.e., those passed down through regular language transmission, and 'borrowed' forms and structures, i.e., those that diffused into a language from an external linguistic system, took on a special significance. This distinction was a key part of the reasoning behind the establishment of regular sound correspondences between two or more languages (and the recognition of regular sound changes that follows from the identification of such correspondences) and of the demonstration of language relationships. To elaborate briefly, the point is that once one is able to isolate across two or more languages words and/or morphemes that are cognate, i.e., that have sprung from the same source and are inherited into each of the languages in question, and that by virtue of their cognacy show systematic correspondences of sound between them, it becomes possible to argue that forms that do not fit the patterns of correspondence may be later entries from some language into one or more of the languages being compared. For instance, a comparison of Latin *dent-* and English *tooth* reveals two consonant correspondences, $d \sim t$ and $t \sim \theta$, that recur in many other words (e.g., ***d**ecem* ~ ***t**en*, ***d**omus* 'house' ~ ***t**imber* ('building' in old English), ***t**res* ~ ***th**ree*, ***t**erra* '(dry) land' ~ ***th**irst*, inter alia) and that therefore provide a basis for determining that matches like ***d**ent-* ~ ***d**ental* or ***t**riplus* ~ ***t**riple* are due to contact-based influence, despite the identity of the relevant elements; indeed, some might say 'because of' rather than 'despite,' on the assumption that with matchings that are identical in one set and nonidentical in another set, the nonidentical ones are more likely to reflect true cognacy and the identical ones more likely to reflect a contact-related development.

This distinction was in part reflected in the controversy in the nineteenth century between the family tree modeling of language relationships, as espoused by August Schleicher ('*Stammbaumtheorie*,' cf. Schleicher, 1853), and the wave theory modeling ('*Wellentheorie*') of Johannes Schmidt (cf Schmidt, 1872). Schleicher's model reflected system-internal innovations that caused breaks in speech communities and ultimately

resulted in splits into multiple dialects and eventually multiple languages, while Schmidt's model reflected innovations that diffused across the (relatively clean) lines of descent of the Stammbaum model, thus marking changes that involved contact between speakers of differentiated speech communities, i.e., that spread through dialect or language contact. Although Schmidt's contact-based model seems to be at odds with Scheicher's line-of-descent model, they are really modeling different kinds of linguistic innovations, essentially changes induced by system-internal factors (Schleicher) and those induced by system-external factors (Schmidt). The importance of recognizing system-external factors is thus set against what is known about language-internal paths to differentiation; as the example of *tooth/dental/dent-* above shows, one can only understand what is due to contact by having a clear picture of what is inherited (and vice versa, one might well say, so that what is inherited becomes clear(er) once what is due to external influence is identified).

Nonetheless, despite the early importance that the recognition of contact between languages has played in the study of language in general but especially the study of language change, it is fair to say that in recent years, the study of language contact has come into its own, aided by the emergence of the study of pidgin and creole languages as a distinct subarea within linguistics on the one hand, and the recognition of the importance of bi- and multilingualism on a psychological and social level on the other. There is now a separate subdiscipline of 'contact linguistics,' complete with textbooks (e.g., Thomason, 2001; Winford, 2003; Matras, 2009), handbooks (e.g., Goebl et al., 1997/2008, Hickey, 2010), specialized studies (e.g., Thomason and Kaufman, 1988; Myers-Scotton, 2002), focused collections (e.g., Thomason, 1997; Siemund and Kintana, 2008), and the like. In what follows, the key concepts and constructs associated with the study of language contact are presented, by way of illustrating and explicating how vital the recognition of language contact is to the understanding of language in general, and how pervasive the effects of language contact can be.

Mechanisms of Language Contact

Language contact must begin with different language systems, and thus with some degree of bilingualism (using this as a cover term for any number of languages involved) either on an individual basis, where one speaker has abilities in two (or more) different languages, or on a societal basis, where groups of speakers of different languages live coterritorially, interacting with one another in the community at large and existing side by side (to be understood figuratively and broadly, so as to cover as well cases in which different language groups are essentially segregated in different parts of a city or region). In cases of individual bilingualism, especially when the speaker in question has a nativelike command of both languages, the language contact can be said to take place in the mind of the speaker. In societal bilingualism, however, the contact takes place between different speakers so that there truly is a social dimension to the contact. But in such a situation, in order for speakers of different languages to interact linguistically, at least one must have to some degree learned the language of the other, and in that phrase 'to some degree,' the seeds of language change through language contact are to be found. It is important to emphasize 'linguistic' interaction, because made-up and highly iconic gestures can be a basis for some communication, much as picture writing can be in the absence of a shared writing system; such gestures would foster communication between groups but without affecting their languages.

That is, in most instances of contact between speakers of different languages, one of the speakers involved is less than fully proficient in the language being used, typically having learned the language as a second language, an add-on to already well-entrenched language abilities. This second-language learning will often have come in adulthood.

At this point, an aside, but an important one, is in order. It is a common observation that younger children and perhaps even teens seem to be able to gain a native or nativelike command of a second language in ways and to a degree that older adults cannot; rather, adults seem generally to struggle with gaining such abilities. And, it is common, though somewhat controversial, to explain this observation in terms of a 'critical period' developmentally for language acquisition that allows younger speakers to gain a native command of a given language; such a period is usually thought to last into one's early teens or thereabouts, so that one could distinguish between the presumably perfect acquisition of a native language and the less-than-perfect command that typically comes with language learning later in life. While this hypothesis is doctrine among some linguists, there are adults who gain such a fine command of a second language that they can pass as native speakers, suggesting that other factors may be involved in second-language acquisition and that the occurrence of differential outcomes for child and adult language learners is not a purely biological developmental matter. That is, differential learning outcomes may not be an effect specific to the learning of language but could be due to differential motivations for learning on the part of the different groups, e.g., just for communication or for social indexing as well, or differential general learning abilities and strategies employed by the different individuals in the different groups.

This said, second-language learning for adults and even for many bilingual children will necessarily involve the second language being learned through the filter of an already existing language system, the learner's native language. This means that a speaker's native language can have an effect on a second language that one comes to speak later in life, after the native language is solidly in place in one's mind. These effects are often referred to as 'substratum effects' (the native language being a substratum that underlies production of a secondarily acquired language) or as 'interference' or 'transfer' effects (the native language patterns interfering with or transferring onto the production of the secondarily acquired language). Such substratum/interference/transfer effects can be observed in the difficulties second-language speakers can have learning to use elements with no direct analog in their native language. At the level of sound, for instance, one can note the persistence of native pronunciation patterns into a second language, i.e., speaking with an 'accent,' as when English speakers have trouble with the voiced velar fricative ([γ]) of modern Greek, and pronounce a name like [andiγóni] ('Antigone') as [andigóni], or Greek speakers have trouble with the voiceless palatal

fricative ([ʃ]) of English, and pronounce a name like [ʃejn] ('Shane') as [sejn], since these sounds are not part of the speaker's native language phonological inventory. Similarly, Russian speakers have trouble learning to indicate definiteness and indefiniteness in English through the use of the articles *the* and *a(n)*, since Russian has no such morphemes, relying instead on word order to express such discourse-sensitive notions.

Such difficulties in second-language learning are ubiquitous and almost inevitable, given that there is always a first language in place when an older speaker learns a second language. Moreover, these effects are important to note, as they give an indication of how a language in the broad sense could be affected by contact. The operative phrase here is 'in the broad sense,' since such substratum interference generally has no effect on the grammars of *native* speakers. Rather, the target language is changed only in the mouths (and minds) of those acquiring and using it secondarily; the French spoken with an American English accent by a university student studying French as a foreign language does not affect in any way the French spoken by a Parisian or by a Quebecois(e). Nonetheless, such interference might be relevant for contact-induced change in a couple of ways.

First, if the numbers of second-language users and their demographic concentration are sufficient, interference on an individual basis, repeated in speaker after speaker coming at the learning of a second language, perhaps out of necessity due to conquest or trade encounters or forced – or even voluntary – relocation, with the same first language background, can lead to the emergence of a new dialect of the target language, and thus to change in the overall makeup of that language. This has been the case with the emergence of Indian English, for instance, and, for that matter, with most so-called 'New Englishes' (see Schneider, 2003).

Second, a powerful force in language contact is accommodation (see, e.g., Giles, 1973; Giles and Johnson, 1987; Sachdev and Giles, 2004, among many other works, for discussion of accommodation), the process by which speakers alter their behavior, in this case their linguistic behavior, in the direction of that of their interlocutor(s), partly to enhance communication and partly to avoid uncomfortable encounters and to promote the saving of face for all participants. Thus a native speaker might well adjust his or her pronunciation of particular words in the direction used erroneously by a nonnative second-language speaker so as not to embarrass the nonnative speaker or draw attention to his or her error. Or, the native speaker might avoid complex syntactic constructions on the assumption that they might be too difficult for the second-language speaker to understand or respond to. In this way, the usage of the native speaker and the second-language speaker might converge in certain respects on the second-language speaker's usage, moving in a direction away from the native norm, or might reach some sort of 'compromise' variety between the two language forms. If the interaction is just a one-off event, there is really no effect on the target (native) language, but if such encounters are commonplace, and again if the numbers of second-language speakers are high enough, there could well be an overall effect on the usage of the native language speakers, especially in mixed company involving both native speakers and second-language speakers.

Another type of interference effect arises in cases in which a speaker is obliged in the society at large to use a language other than his or her native language on a regular basis, to the extent where the second-language patterns affect the native language patterns for that individual. Such effects can be called 'reverse interference' (see Joseph, 2009; Friedman and Joseph, 2015: Chapter 3), since it is the reverse of the more usual substratum situation described above. Cook (2003: 1) calls it 'backward transfer,' also 'reverse transfer', but 'reverse interference' is preferable because it does not always involve the transfer of features per se, but can involve just some influence (as with the Portuguese-on-English example given below).

Although not as well studied as substratum interference, reverse interference is no less real. A well-known case has to do with voice onset time (VOT), as described by Major (1992), who discovered that native speakers of English living in Brazil, i.e., in a Portuguese-dominant environment, showed VOT in their English stops that approximated but did not necessarily match exactly the Portuguese VOT, thus a sort of compromise between English and Portuguese VOT. Similarly, Hussein (1994) demonstrated that native Arabic speakers immersed for many years in an English-dominant environment had English-like vowel lengthening before voiced stops in their Arabic. Such 'reverse' effects also show up in speech perception; Caramazza et al. (1973) found that French–English bilinguals perceived stops in both languages in terms of the VOT of their second language, English, even though they did not show reverse production influence from English into their French, suggesting that this overall phenomenon is perhaps more complex than might first be supposed. A final example shows that reverse interference effects can be found in syntax as well as in phonology, for Young People's Dyirbal (YD), as described by Schmidt (1985: 230), shows evidence of English word order in the productions of YD speakers, saying "the exceptionally-free T[raditional]D[yirbal] word order is rigidified in YD as an A[gent]-V[erb]-O[bject] pattern as in English."

As mechanisms of change through language contact, interference (substratum/transfer) and reverse interference are not completely distinct. They have in common, of course, the fact of one language affecting another, but it may be a matter in each of the dominant language affecting the lesser one; 'dominant' here does not mean socially dominant, but rather cognitively or psychologically dominant in the perception of the individual speakers. Thus, what might make it possible for a speaker's native language to be affected by a secondarily learned language is that the speaker uses the second language in a wide range of contexts, almost to the exclusion of the native language. That is, native language attrition may be involved with the second language becoming the speaker's default language. In this way, the social dimension of bilingualism and the individual dimension converge, make possible change within the individual, and therefore change within the social group as well.

Manifestations of Language Contact

As the discussion in the previous section indicates, the main manifestation of language contact is the influence of one language system over another. The most straightforward effect is addition to the lexicon, what is traditionally called 'borrowing,' producing 'borrowings' or 'loanwords.' Terminology referring to 'borrowing' or 'loans' is widely used, but

is infelicitous for various reasons. For one thing, the donor language does not 'lose' anything and is not diminished in any way and 'borrowed/lent' items/features are not returned. One might make an exception to this latter claim in the case of reborrowings, where a word passes from one language into another and then, at a later stage back into the original donor language, as with English *tennis*, originally from French *tenez*! 'hold! receive!,' but now the source of present-day French *tennis*; however, even in such a case, there is really only a historical oddity to marvel at, not an overt decision by speakers to give back and thus repatriate some word or other. Furthermore, as traditionally used, 'borrowing' was (almost) exclusively lexical in nature (as suggested also by the other term, 'loanword'); linguists have come to realize, though, that more can be passed ('borrowed/lent') between languages than just lexical items, as is discussed more fully below. Despite the shortcomings of the traditional terminology, its use is commonplace, and not likely to change any time soon.

Loanwords have been classified in various ways. One classification schema focuses primarily on the form of the loan. Haugen (1950), for instance, drew a difference between 'importation' and 'substitution,' where the key distinction is whether markers of foreignness are present (in 'importations') or not (in 'substitutions'). English borrowings from Norman French with initial *v*-, like *veal*, would be importations, since the French sound was maintained more or less as is, even though at the time of borrowing, [v] was not found word-initially in English. A recent borrowing into English from (Mexican) Spanish such as *taco*, with aspirated [t^h] in the English in place of a Spanish unaspirated [t], which does not occur in initial position in English, would be an example of a substitution.

There can also be classification based primarily on the content of the loan, as in the schema of Bloomfield (1933). Bloomfield's distinction was between, on the one hand 'cultural borrowings,' those arising via the exchange, often mutual, of terminology for culturally based objects between speakers of different languages representing different cultures, as with many English words from American Indian languages, such as *moccasin*, from an Algonquian language designating at first just the soft leather shoe worn by the Indians, and on the other hand 'intimate borrowings,' those not obviously linked to cultural objects, such as *veal* noted above. Additionally, there can be classification focusing primarily on the motivation for the loan, as in the schema of Hockett (1958), who distinguished between 'need borrowings,' echoing Bloomfield's cultural type, but with the motivation of 'needing' a word for a (new) cultural item at issue, and 'prestige borrowings,' where the motivation is the 'prestige' that the borrowing language speakers accord to material from the donor language.

These typologies have been quite influential, but are not without some problems. For one thing, by focusing on form, Haugen's classification does not build in the social context for the loans, even though there is almost always the social dimension to borrowing of contact between speakers. An exception to this latter statement must be made for so-called 'learnèd borrowings' from an earlier, often (perceived as) stylistically elevated, stage of a language, as seen, for instance, in Latin borrowings into Romance languages, such as Spanish *digito* 'digit, number' from Latin *digitum* (here Spanish also has the form that developed by regular sound changes from *digitum*, namely, *dedo* 'finger'), and also in the Bulgarian and Russian use of Church Slavonic words, the adoption into Modern Greek *dimotiki* (low-style, colloquial language) of *katharevousa* (high-style, ancient-Greek-based) words, or Sanskritisms in modern Indo-Aryan languages (so-called 'tatsama' words). Moreover, the types listed above are not necessarily discrete; a cultural/need loan might be undertaken for reasons of (Hockettian) prestige or be associated with (Bloomfieldian) intimate contact. Also, noncultural/nonneed loans are not always a matter of prestige, at least not obviously so. For instance, the Albanian dialect of Greece known as Arvanitika, spoken in Greece for some 600 years, is the source of the diminutive suffix *–zə* that occurred in the early twentieth century at least in the Greek town of Megara, in Attica, as in *liγaza* 'a little,' formed from Greek *liγa* 'a little' with the Arvanitika diminutive added on; this occurred even though Albanian, and Albanians, have never been accorded much overt prestige by Greek speakers.

One may do well, then, to recognize a type of loanword that goes beyond these classificatory boundaries and focuses on the milieu in which the borrowing takes place. Friedman and Joseph (2014, 2015), for instance, have suggested that the medium of conversation must be recognized as crucial in borrowings and that in face-to-face interactions of an ongoing and sustained sort, various types of conversationally rooted borrowings transcending need or prestige and emerging just from repeated conversational encounters will occur. Such loans can be referred to as 'ERIC' loans, an acronym for 'essentially rooted in conversation' (that also honors Eric P. Hamp, historical linguist and contact linguist (and Balkanist) par excellence). Discourse-based items such as confirmatory words, hedges, attitudinal markers, and the like can be borrowed in such circumstances. In the Balkans, for instance, one finds 'yes' passing from Slavic (*da*) into Romanian and from Greek (*malista*) into Aromanian as well as negatives being borrowed, as with the Greek prohibitive negator *mi* 'don't…!' and the negative word *oxi* 'no' entering Southern Aromanian (as *mi* and *ohi*).

Further, there are some forms that are inextricably tied to conversation. For instance, a vocative element signaling unceremonious address, rather like 'hey you' in English, has spread all over the Balkans from a Greek starting point (with most forms deriving ultimately from the ancient Greek *mōré*, vocative of 'foolish'), as discussed in Joseph (1997); a sampling of the relevant forms is as follows:

Turkish	*bre*, *bire*, *be*
Albanian	*ore*, *or*, *mor*, *more*, *moj*, *ori*, *mori*, *moré*, *mre*, *voré*, *bre*, *be*
Aromanian	*More*, *mori*, *bre*, *be*, *or* …
Romanian	*bre*, *mă*, *măi*
Bulgarian/ Macedonian	*more*, *mori*, *bre*, *be*, *or* …
Romani	*more*, *mori*, *bre*, *be*, *or* …
Greek	*moré*, *bre*, *vre*, *re*, *aré*, *maré*, *marí*, *oré*, *voré*, *or*, *mor*, *mo*, etc.

Also, there are exhortatives, rather like English 'c'mon,' that have spread widely, such as Albanian, Bulgarian, and Macedonian *ela* 'c'mon' from Greek *ela* 'c'mon,' or the widespread *(h)a(γ)de*, from Turkish *(h)aγ de*.

Another classificatory schema for loanwords has to do with what is referred to as 'borrowability,' and it is suggested that there are some words that are less likely to be borrowed. At least as far back as Swadesh (1950) and his list of basic vocabulary items, linguists have worked with the assumption that a core of basic lexemes would be more resistant to borrowing than nonbasic items; this core varies from linguist to linguist, but includes items such as primary body parts ('head,' 'foot,' 'mouth,' etc.), omnipresent aspects of the natural world ('sun,' 'water,' 'cloud,' etc.), basic verbal actions ('eat,' 'say,' 'sit,' etc.), immediate kinship terms ('father,' 'mother,' 'brother,' etc.), and various closed-class or grammatical forms such as numerals, pronouns ('I,' 'this,' etc.), adpositions, complementizers, connectives, and the like. Still, it is possible to find examples of the borrowing of such items: kin-term loanwords occur among languages of the Balkans, e.g., Turkish *baba* 'father' ⇒ Greek *babás*, Albanian *baba*; Greek *patéra* ⇒ Aromanian *patera*; Turkish *dayı* 'maternal uncle' ⇒ Albanian *dajë*, Macedonian *daja*, as do pronominal loans, e.g., Greek *m(u)* 'my' ⇒ Aromanian *–m;* Turkish *bu* 'this' ⇒ Ottoman-era Edirne Greek *bu* 'this'; postpositions, e.g., Turkish *karşı* (*karşi* in Balkan Turkish) 'opposite' ⇒ Albanian, Aromanian, Bulgarian, Macedonian, and Ottoman-era Edirne Greek *karshi* (spelled differently in the various languages so that 'karshi' here is a cover form for various similar-sounding realizations of the Turkish word; it is noteworthy that the Aromanian and Greek forms were used as postpositions, while in the other languages, the form was adapted to the native pattern of prepositional use); numerals, e.g., Greek *efta, oxto, enja* '7, 8, 9' ⇒ Romani *efta, ohto, enna/enja*; complementizers, e.g., Turkish (<Persian) *zira* (std), *zere* (dial) 'because' ⇒ Bulgarian and Macedonian *zer* (with variants *zerem, zare, zerja, zeri*); as well as connectives, e.g., Macedonian *i* 'and' ⇒ Aromanian and Romani *i*.

Some linguists have seen constraints on borrowing as tied to the grammatical nature of the element, with bound morphology, both derivational and inflectional, being hard to borrow. Yet once again, counterexamples can be found. The Turkish agentive/occupational suffix *–çI/-cI* (the symbol *–I* here represents a high vowel that harmonizes for frontness and rounding with the final vowel of the stem that the suffix attaches to) has spread all over the Balkans (cf Greek *taksi-dzis* 'taxi driver,' Macedonian *lov-džija* 'hunter'), and the Turkish plural suffix *–lar/-ler* still occurs in present-day Albanian (e.g., *baballar* 'fathers,' *efendiler* 'sirs') and could be found in wider use as well in nineteenth-century Bulgarian.

One element of the debate over constraining borrowing has focused on whether only concrete material can be borrowed or whether structural aspects of a language can also be affected by contact with another language. Clear examples of structural patterns passing from one language to another, sometimes running counter to trends in place in the borrowing language, however, can be found. Turkish borrowed finite complementation with the complementizer *ki* from Persian, in contradistinction to the otherwise nonfinite-only complementation patterns in the language, and postpositional borrowing into prepositional languages is noted above, with Turkish *karşı* and in Ottoman-era Edirne Greek with Turkish *gibi* 'like' also. And, going beyond just the borrowing of the syntactic requirements of a lexical item along with the item itself, it has been argued that the wholesale replacement of nonfinite complementation by finite complementation in the Balkans, a characteristic found especially strongly in Albanian, Aromanian, Bulgarian, Greek, Macedonian, and Romani, and also in western Rumelian dialects of Turkish in contact with Greek and Bulgarian, is due to intensive contact among speakers of these languages, with modeling and copying of finite structure, even down to details as to the kinds of complementation (indicative as well as subjunctive), and accommodation to nonnative varieties both playing a role in the transfer of innovative patterns from one language to another (see Joseph, 1983/2009 for discussion).

Seeking constraints of a purely linguistic nature on borrowing and on transfer across languages more generally, therefore, may be an exercise in futility. Rather, it may well be, as Thomason and Kaufman (1988) claim, that under the right social conditions (e.g., having to do with intensity of contact), anything can be borrowed. The prevalence and apparent ease of lexical borrowings, therefore, as well as the seeming greater difficulty in borrowing bound morphology and structural patterns, may simply be a function of the fact that the social conditions leading to the intense contact needed for borrowing of morphology and syntax arise less often than the casual contact needed for lexical borrowing.

As a final point regarding lexical borrowing, it should be noted that besides loanwords per se, there are other kinds of lexical effects arising from language contact. In particular, contact can lead to loan translations, also known as 'calques,' in which the structure of a word in the source language is copied in the borrowing language but realized with native language material. For instance, Latin *compassio* 'compassion' was the model for German *Mitleid*, based on an equating of *com-* with *mit-* and *passio* with *leid-*. Even phrases can be calqued; English *it goes without saying* is a calque on the French *il va sans dire*, where the odd diathesis of the English (in particular, passivelike meaning but not passive form, i.e., not '… without being said'), can be attributed to the French model (where such diathesis is normal). It perhaps goes without saying here that calquing requires a certain degree of bilingualism on the part of the recipient language speakers, for otherwise the morpheme-by-morpheme or word-by-word identifying and translating would not be possible. A more subtle kind of lexical effect is seen in 'loan blends,' or 'hybrid' forms, where a slight or partial effect can be detected; for instance, in the Greek of southern Albania, the adjective *ekonomikós* 'economic,' with initial *e-* instead of the expected *i-* (as in standard Modern Greek, *ikonomikós*), seems to be a result of influence from Albanian, where the corresponding adjective is *ekonomík* – the placement of the stress in Greek reveals that this is not just a wholesale borrowing from Albanian but rather shows Albanian initial vocalism grafted onto the Greek word. Similarly subtle, but no less real, is contact-induced 'iso-semy,' where meanings shift in one language under the influence of the semantics of parallel forms; for instance, Greek *anixto-*, literally meaning 'open(ed),' is used with color terms to mean 'light-' (e.g., *anixto-kokino-* 'light red'), apparently due to the influence of the parallel use of Turkish *açık* 'open,' and also 'light-' with colors.

Effects of Contact

One common outcome of contact is simplification, and particularly striking in this regard is the creation in certain contact situations of pidgin languages - somewhat streamlined and highly simplified versions of linguistic systems put to use for rudimentary but essential communication, for instance, when commerce is involved, between groups of speakers having no common language between them. But contact can also lead to complexification, not just when pidgins are expanded functionally to other situations and become elaborated grammatically as creoles, accommodating to new functions, but also when borrowing brings in new structural possibilities alongside existing structures and adds expressive possibilities to a language. Thus it is probably safer to give the most typical outcome of contact-induced change as convergence between the languages involved. The term 'convergence' is used here to refer to an outcome of similarity between two languages, but it can also, sometimes somewhat confusingly and thus unfortunately, be used for the process by which such similarity arises. Convergence means that via borrowing, interference, transfer, calquing, and blending, languages in contact come to be more like one another along particular parameters, whether it is a matter of shared sounds or sound patterns, shared structures, shared words, shared phraseology, or whatever. The convergence is not necessarily unidirectional, of course, as the discussion above indicates, but convergence it is.

In some instances, the convergence is so great and to such a pervasive degree that the languages affected by contact seem to share a significant proportion of their structure. In such cases, especially where there is multilateral and multidirectional multilingualism and more than just casual contact, but rather sustained contact on an ongoing intimate, conversational basis, one can find a whole group of languages that come to share structure as well as lexical items. Such widespread areal convergence is often referred to as a 'sprachbund' (a borrowing from German) or 'linguistic area,' and while several sprachbunds (some linguists borrow the German plural here, *Sprachbünde*) have been identified around the world, e.g., in South Asia, in the Pacific Northwest of North America, in the Amazon, and elsewhere, the best known and most studied such convergence zone is the Balkans, where languages alluded to repeatedly herein – Albanian, Aromanian, Bulgarian, Greek, Macedonian, Romani, and (Western Rumelian dialects of) Turkish – converge not only on numerous lexical items of a noncultural sort but also on numerous points of structure including:

1. a reduction in the nominal case system, especially a falling together of genitive and dative cases;
2. the formation of a future tense based on a reduced, often invariant, form of the verb 'want';
3. the use of an enclitic (postposed) definite article, typically occurring after the first word in the noun phrase;
4. analytic adjectival comparative adjective formations;
5. marking of personal direct objects with a preposition;
6. double determination in deixis, that is a demonstrative adjective co-occurring with a definite article and a noun (thus, 'this-the-man');
7. possessive use of dative enclitic pronouns;
8. the use of verbal forms to distinguish actions on the basis of real or presumed information source, commonly referred to as marking a witnessed/reported distinction but also including nuances of surprise (admirative) and doubt (dubitative);
9. the reduction in use of a nonfinite verbal complement ('infinitive') and its replacement by fully finite complement clauses;
10. the pleonastic use of weak object pronominal forms together with full noun phrase direct or indirect objects ('object doubling'); and
11. the formation of the 'teen' numerals as DIGIT-'on'-TEN.

And there are far more convergent features when one looks just at the Balkans in very localized pairs or triples of languages rather than aiming for a broader coverage. This has led some researchers, most notably Friedman and Joseph (2015), to argue that even two languages can form a sprachbund, if enough convergence is observed, and that the difference between intense contact involving two languages and the sprachbund sort of convergence effect is a matter of difference of degree not difference of kind. Again, the social conditions on the ground are the key to the outcome, not some predetermined or arbitrary limit or constraint that a linguist might want to impose.

For all the fact that contact so often leads to convergence, there are contact situations in which the outcome is divergence between the languages involved, or at least, a failure to converge. In the Balkans, even with all the convergent forces at work, and even with considerable shared structure between Romani and other Balkan languages, Romani phonology has maintained its distance from the phonology of other coterritorial languages. In particular, Romani still has its voiceless aspirated stops, and thus diverges from the other languages in the region as being the only language in the Balkans with distinctively aspirated stops. It is not that phonology is immune to contact effects: the Aromanian spoken in Greece, for instance, has adopted Greek fricatives in loanwords without nativizing (substituting for) them and the fricatives have spread into some native Aromanian words even; the same can be said for some of the Macedonian dialects in Greece and Albania). Rather, it is the relative social isolation of Romani speakers and the one-way bilingualism that characterizes interactions the Roma have with speakers of other languages may have helped to promote the maintenance of a distinctive Romani character through its phonology, with the social factors therefore contributing to divergence as an outcome of contact. Once again, the social dimension cannot be ignored in a full consideration of what goes on in a language contact situation, and may be more of a determinant than anything purely linguistic in nature.

Conclusion

To sum up, it must be admitted that contact between speakers is a powerful force in shaping languages and thus language contact is an important synchronic fact about speakers' lives as well as an important force in language change, leading to what is referred to as 'externally driven' or 'externally motivated'

change. But in a sense it must be seen as intrinsically connected to internally driven change, what Andersen (1973) refers to as 'evolutive change,' not wholly divorced from it (Andersen (1973) refers to contact-induced change, or at least one manifestation of it, namely, dialect contact, as 'adaptive' change; Labov (2007) uses the rather apt terms 'transmission,' for internally driven change, and 'diffusion,' for externally motivated change). That is, establishing a genealogical relationship between languages is only possible if the correspondences observed between languages that are due to contact (borrowing) can be sifted out so that the inherited correspondences can be detected. Similarly, the contact-induced correspondences stand out only once a reasonably clear picture is developed of what the inherited material in a given language is. Thus the two types of historical connections between languages, a genetic/genealogical relationship and a contact relationship, are complementary, not competing, ways of modeling language history, and can be seen as two sides of the same coin, what Hamp (1977) has called the 'twin faces of diachronic linguistics,' as both are needed in the elucidation of the sources of similarities and differences between languages observable today. Even with the emphasis here on the Balkans (due in large part to this being the region where the author's expertise lies, though as a hotbed of language contact, the Balkans represent one of the best exemplars from which to draw general lessons about contact between speakers of different languages), it should be clear that the recognition of language contact enriches not only the historical understanding of languages but also the synchronic understanding.

Abstract

Language acquisition by children is robust. Even children with relatively limited exposure to adult speech acquire the major properties of their native language early in childhood. Theoretical approaches to language development have emphasized our biological preparedness for language, the speech presented to children, children's cognitive readiness, and their ability to identify regularities in the speech signal. Contemporary research suggests that several interacting factors are likely to be responsible for children's language acquisition. At the same time, there has been a renewed interest in the biological foundations of language, albeit with an emphasis on the social dimensions of language.

A variety of theoretical approaches to language acquisition have emerged in recent decades. Although the field was initially the province of nativist approaches that claimed an innate basis for language acquisition, in recent years, a diverse array of views have been discussed and debated. Despite the absence of a clear consensus on theoretical matters at the present time, some of the elements of a comprehensive model have come into view. In this article, we consider five theoretical approaches to language acquisition: nativism, child-directed speech, statistical learning, lexical stress, and cognitive development.

Nativist Approaches

The nativist approach to child language emphasizes the role of innate factors in language acquisition (Lenneberg, 1967). The approach most often is associated with the linguist Noam Chomsky, who has asserted that child language acquisition cannot be explained entirely by reference to children's language experience. Chomsky's primary argument for the nativist position has been *the poverty of stimulus argument* (Chomsky, 1980). This argument claims that there is not enough information in the language that is presented to children to enable them to infer the underlying properties of their native language. As a consequence, Chomsky concluded that children needed to have some innate knowledge that, together with the data acquired from the environment, enables the child to acquire the native language.

Several different sources of data have been used to support the nativist explanation. Bickerton (1984) has examined the language of agricultural workers brought into Hawaii to work on sugar plantations. Because the workers were not fluent in the native language, they needed to acquire as much of the language as they could on the fly. What resulted was a *pidgin*, a rudimentary form of language that exists when speakers of mutually unintelligible languages are in close contact with one another. Pidgins are a linguistic free-for-all, with word order often based on the speakers' native language. Interestingly, children of these immigrants developed *creoles*, which were grammatically more sophisticated. The observation that children of immigrants, receiving rudimentary language exposure, were able to produce a more complex version of language than their parents suggested to Bickerton the presence of an innate grammatical system that guides language acquisition.

Similar conclusions emerged from the work of Goldin-Meadow (1982) with congenitally deaf children between 13 months and 4 years of age. Although the children were not exposed to any conventional sign language, they developed their own form of sign language, which was called *homesign*, which shared grammatical properties with signed and spoken languages. Moreover, the milestones that children achieved in homesign (e.g., one-sign utterances about 18 months, followed by two- and three-sign utterances) were similar to those achieved by children exposed to sign. Goldin-Meadow concluded that when language experience was minimal, deaf children might create a gestural system that shares many of the properties with sign languages.

Additional evidence for the nativist view came from studies of sign language acquisition in Nicaragua. The studies took advantage of some political changes in the country in the late 1970s, when the Sandanistas took over control of the government but provided no formal education for deaf children. As with the homesign children, Nicaraguan children began to develop a rudimentary sign system that resembled a pidgin language. Children exposed to the pidgin sign language, however, appeared to acquire a more full-fledged sign language similar to the creoles studied by Bickerton. Whereas the pidgin sign varied considerably from user to user, the creole sign was more consistent. These observations, coupled with those of Bickerton and Goldin-Meadow, suggest that, in situations in which language exposure is limited, individuals are capable of developing or creating a form of communication approaching a full-fledged language.

Although these studies are an important source of data, they pertain to fairly extreme degrees of environmental language neglect. Thus, they leave open the question of to what extent more mundane language experience may shape language acquisition in children. That is, can we identify any relationships between the type of language that parents typically provide to their children and the child's subsequent acquisition of language? The poverty of stimulus argument represents a challenge for more environmentally oriented theorists to demonstrate that the language ordinarily presented to children guides the child's language progress. One line of approach is represented in the next section, when we consider the nature and impact of child-directed speech.

Role of Child-Directed Speech

Parents speak differently to children acquiring language than they do to older children or adults. There are modifications in adult speech to children at every linguistic level. Adults use exaggerated intonation, clearer articulation, shorter sentences, and a greater number of diminutives (e.g., *doggie*) when speaking to children. They also show a greater preponderance of directives and questions than is common in adult speech. Several of the aspects of child-directed speech (sometimes called *motherese*) appear to have the effect of attracting and maintaining the attention of young children. Others may serve to direct or control the behavior of children.

A more challenging question is to assess the effect of child-directed speech on language acquisition. Gathercole and Hoff (2007) identified three central questions pertaining to the impact of language input on language acquisition. First, what information about grammar can the child extract from child-directed speech? At present, there is little evidence that language input promotes language acquisition. For example, although there is some evidence that shorter sentences may promote acquisition, several studies instead suggest that presenting children with longer utterances advances their syntactic development.

Child-directed speech also provides an opportunity for children to receive corrective feedback on their utterances. For example, when a child uses an ungrammatical form, parents may provide feedback in the form of more grammatically correct language. The data on this issue, however, are not clear. Some studies suggest that parents are more likely to correct their children's utterances on semantic rather than syntactic grounds, thus providing minimal support for grammatical development. Other studies found that adults sometimes provide subtle feedback that provides an opportunity for children to recast their utterances in grammatical form. Even here, though, it is unclear whether the feedback is provided often enough to facilitate grammatical acquisition.

Studies that suggest that the input children receive may serve as data for distributional learning may be more promising. For example, children acquiring English will be exposed to numerous utterances that conform to the grammatical requirements of the language. Children gradually may induce these grammatical properties over time. Thus, English-speaking children often will hear utterances in which the word *a* is followed by an object (e.g., *a bird*), whereas the word *some* is followed by a substance (e.g., *some playdough*). Such regularities permit the child to infer some of the basic grammatical properties of the language from the input they receive. How children might do so is discussed more fully in the section dealing with statistical learning.

A second question is whether child-directed speech controls either the sequence or the speed with which children construct the grammar. Regarding sequence, the question is whether the order in which children acquire different aspects of language can be predicted from their frequency of use. For example, we know that English-speaking children acquire the active voice prior to the passive voice and that the active voice is much more common in adult speech. Children learning languages in which the passive voice is more common, however, appear to acquire the construction more rapidly, suggesting that input may influence the developmental sequence. On the other hand, studies of the child's acquisition of grammatical morphemes, however, do not support the assertion that frequency of input is the primary factor in the timing of acquisition. English-speaking children typically acquire these morphemes based on their linguistic complexity more than their frequency of presentation to children. For example, the plural morpheme (*balls*), which encodes the notion of number, is typically acquired earlier than the third-person regular tense (*he works*), which encodes both number and time.

There is more support for the notion that input influences the speed of acquisition. Here studies of bilingual children are most revealing. English-Spanish bilingual children show greater facility of language with English when they had the greatest amount of input in English, and the reverse is true for those who more commonly heard Spanish. These results converge with those just discussed that suggest that frequency of usage – rather than more active processes, such as corrective feedback – may provide important clues for the child's construction of grammar.

Third, is the speech presented to children sufficient to explain the child's acquisition of grammar? Few scholars beyond diehard behaviorists believe that input is sufficient to explain the child's language acquisition. Gathercole and Hoff identified two important factors – cognitive understanding and linguistic complexity – that also play a role. Grammatical features that encode complex concepts typically are acquired later, regardless of input. Moreover, how concepts are encoded in the language matters: When a concept has a more complex expression in a given language, acquisition is slower. For example, a *wh*-question in English such as *Why won't Harold call me back?* is syntactically complex, requiring speakers to begin with a *wh*-word (*who, what, where*, etc.), invert the noun phrase and auxiliary verb, and negate the auxiliary verb. Other languages may encode such questions through the simpler process of elevated intonation at the end of the sentence. All things equal, when the expression is more complex, acquisition is slower.

On balance, recent research suggests an increasing acceptance of the role of input and the declining support for the nativist view. This development, however, is tempered with the recognition that input is not sufficient. We also need to understand how child-directed speech interacts with the linguistic complexity of the forms and the cognitive preparedness of the child. Nonetheless, there is increasing recognition that children are able to acquire key aspects of language from the data they routinely experience.

Statistical Learning

Statistical learning mostly has been used to investigate whether statistical regularities within a language can explain some aspects of language acquisition with experientially developed expectancies. Simple frequency of an item is not enough for statistical learning to occur. Instead, a transitional probability must be used (transitional probability equals frequency of cooccurrence of two stimuli divided by the total frequency of one of the stimuli) to examine whether statistical patterns could serve as a cue to word boundaries. Infants can

successfully exploit statistical cues such as transitional probabilities to determine word boundaries. When first described in the mid-1990s, statistical learning offered a unique and important contribution highlighting the crucial role that experience can play in language acquisition – this includes the novel suggestion that language acquisition may not be purely innate. In contrast to Universal Grammar, proponents of statistical learning argue that learning is central to language acquisition and that learning mechanisms based on statistical regularities explain similarities across languages. Also suggested is that language learning is constrained: Listeners are attuned to certain types of probabilities and dependencies but not others. This portion of the theory examines how listeners are able to find reliable statistical patterns that will aid them in statistical learning and ignore spurious correlations. Although statistical learning seems to be effective for all ages, attentional resources do seem to be crucial for statistical learning.

Statistical learning uses innate learning mechanisms to find statistical regularities in a stimulus, exploit these regularities and process the signal using the regularities. Although other types of stimulus-dependent learning (e.g., perceptual learning) is fairly clear that the underlying changing representations are phonemic (or featural) in nature, statistical learning does not make a precise prediction about the nature of representations. Some theorists have argued that the statistical regularities extracted from the signal are abstracted. These theories, however, claim that it is the statistical regularities that are abstracted and not specifics about the language or grammar that is being learned.

Not surprisingly, research on statistical learning also has examined the degree to which learning can be generalized. This research generally has focused on what is called algebraic learning: learning nonadjacent predictive dependencies. Seven-month-old infants could learn simple 'sentences' (with a pattern of ABA or ABB) made of nonsense syllables. Infants could discriminate between grammatically consistent items and ungrammatical items at test – even when they were tested on novel stimuli. This suggests that the learning of predictive dependencies (statistical or algebraic) can be generalized to novel stimuli.

Statistical learning tends to be flexible in the degree of consistency needed for learning to occur. Twelve-month-old infants presented with an artificial grammar still showed learning effects when only 83% of the stimuli was of the same pattern (17% of the stimuli were taken from a different artificial grammar). The tolerance to conflicting cues, however, does have a limit and learning was impaired when infants heard an artificial grammar that was consistent only 67% of the time (with 33% different artificial grammar). Similarly, Saffran et al. (1996) found that transitional probabilities do not need to be perfectly predictive for statistical learning to occur. In a forced choice test between words (tp = 0.31–1.0), part words (tp = 0.1–0.2), and nonwords (tp = 0.0) listeners showed sensitivity to transitional probability. Participants could better distinguish words from nonwords than words from part words. The higher the transitional probability for the words, the better participants were able to discriminate words from nonwords and part words – however, learning of the words was demonstrated even at lower transitional probabilities.

Statistical regularities in language beyond transitional probabilities and algebraic rules facilitate language acquisition. For example, probabilistic phonotactics is the occurrence or cooccurrence of a phoneme(s) within a word in a given position. Phonotactics is specific to a language and phonotactic probability can range from zero (for illegal phoneme combinations) to much higher (for frequently cooccurring phonemes). Knowledge of phonotactics is available very early in language development. Nine-month old infants listen longer to lists of nonwords that are consistent with the phonotactic rules of their native language (e.g., English-learning infants would listen longer to 'spoll' than to 'mboll' because 'mb' is an illegal word onset in English). Even before speech production, infants are sensitive to the phonotactic rules and combinations that govern their language. Infants, however, are not just sensitive to legal and illegal sound sequences, they also are sensitive to phonotactic probabilities. For example, 9-month-old infants prefer to listen to monosyllables that occur frequently in their native language (have a high phonotactic probability) than monosyllables that occur infrequently (have a low phonotactic probability). The low phonotactic probability monosyllables *did* meet the legality constraints of the infants' native language – this indicates that infants are sensitive to more fine-tuned phonotactic detail than simple gross measures of legality. In general, children under the age of six are able to learn high phonotactic probability nonwords faster than low phonotactic probability nonwords. One potential reason for better learning of the high-phonotactic-probability nonwords is that they sounded 'word-like' due to their high probability, and this facilitated word learning in the children. The low-phonotactic-probability nonwords, however, did not sound like existing words and were ignored as unlikely to be relevant linguistic stimuli. This suggests that phonotactics might be used as a metric in word learning and lexical decision tasks.

Statistical learning is not without its critics though. Johnson and Jusczyk (2001) have argued that although statistical learning may have some predictive power, there is more to speech segmentation than statistics. In the same paradigm as the previously mentioned statistical learning studies, when given a choice, infants relied more heavily on stress cues and coarticulation cues than statistics. These results seem to indicate that listeners use all cues available to them. This finding is not really condemning statistical learning, but rather it points out how robust language learning is and how language processing relies on more than one cue.

Lexical Stress

Stress is a potentially rich source of linguistic information about speech that may be fruitful for language acquisition. In a general linguistic sense, stress refers to the accentuation of a unit within a larger context (e.g., syllables within a word or words within a sentence). The focus of the current section is lexical stress or the syllabic stress patterns within a word. The stressed syllable within a word varies from other syllables on some objective measures: pitch (fundamental frequency), loudness (amplitude of the speech signal), and utterance timing (durational patterning). There are a variety of ways that

lexical stress may influence speech perception. Stress can help a listener correctly discern the meaning of a word. For example, if we consider 'contract' to be a noun, the stress is on the first syllable (*CONtract*); if, however, we use the verb form, the stress falls on the second syllable (*conTRACT*). Overall, these quantitative differences make syllable stress a salient cue within the speech signal. The salience has led to the hypothesis that stress plays a crucial role in the segmentation of words within the speech signal.

Although the segmentation of words within a larger linguistic context seems like an easy task, it is not. Speech's actual acoustic signal contains no silences or inherent cues to word boundaries. This lack of invariance in speech has been a cornerstone of the speech perception literature since its inception. Similarly, the invariance problem poses a significant challenge to models of language acquisition. Given the lack of consistency in the speech signal, how are infants able to acquire the language? One early solution to this problem was the idea that lexical stress may serve as a cue to word boundaries. In English, more than half of polysyllabic words have an initially stressed syllable. (This proportion is even higher in other Germanic languages, notably Dutch, Icelandic, Czech, and German. Uralic languages such as Finnish and Hungarian also have high proportions of primary syllabic stress.) Other languages, such as Polish, typically contain a stressed penultimate syllable. Regardless of language, lexical stress often can provide valuable information into the location of word boundaries.

Lexical stress may be an important cue for language acquisition, but what information are infants extracting from their native language? One specific theory that addresses this issue is the native-language acquisition hypothesis. This hypothesis posits that the initial sensitivity that infants show to rhythmic class forms the basis for learning about the larger rhythmic structure of the language. This rudimentary knowledge about the language structure could allow for infants to use rhythmic cues to segment speech.

The stress pattern of stimuli also may influence the perception of individual phonemes. For example, when presented with a stimulus with initial syllabic stress, native English speakers were able to identify a target phoneme more quickly than if the initial syllable was unstressed. The decreased reaction time occurred regardless of whether the phoneme occurred in a stressed or an unstressed syllable. Other evidence, however, suggests that individual phonemes are identified more easily if they occur within a stressed syllable (perhaps due to the acoustic dimensions of stress discussed earlier). Overall, however, stressed syllables are judged as clearer and more intelligible than nonstressed syllables when excised from their surrounding linguistic context. Taken together, the enhanced perception of stressed syllables offer insight into why stress is a reliable cue for determining word boundaries.

Together with other cues within the speech signal, stress may aid in the acquisition of language. Infants show a remarkable sensitivity to stress patterns within words very early in life. In the first few days of life, infants can discriminate between stressed and unstressed syllables. One important study examined infants' preference for words with a stress pattern that mirrored their native language. Jusczyk et al. (1994) found that English-learning 9-month-old nonspeaking infants listened longer to words that had a strong initial syllable (this pattern, however, was not found in 6-month-old infants). Together, these findings suggest that infants' preference for their native language's stress pattern is determined by their experience with the language (and not an innate preference). This listening pattern and preference may be rudimentary evidence for how infants initially learn to segment words from the larger speech signal.

As infants' develop their linguistic skills, however, lexical stress plays a decreasing role in segmentation and recognition. Later work by Jusczyk et al. suggests that by 11 months of age, infants are no longer relying exclusively on lexical stress to determine word boundaries. As the infants' understanding of the language increases, they begin to rely on multiple cues to determine word boundaries. The salient nature of lexical stress may be an important initial cue to word learning that serves as a bootstrap to learning other cues that may aid in speech perception.

For example, the statistical regularities within words and this regularity may be even more crucial when combined with lexical stress. Using the same paradigm as Saffran's statistical learning, when given a choice, infants relied more heavily on stress cues and coarticulation cues than statistics. Other work demonstrates that when linguistic cues are inconsistent (phonotactic and statistical information conflicts with stress pattern), infants will use stress cues to determine word boundaries and will ignore the conflicting cues. Similarly, the acquisition of an artificial lexicon was influenced by the lexical stress patterns of the stimuli. Stimuli with stress patterns that are consistent with the language learner's native language were more easily learned. Stress pattern might be a crucial cue for word segmentation and may trigger some form of word learning mechanisms. Similar data with adult listeners is consistent with the hypothesis that listeners rely on stress patterns. When listeners are presented with nonsense consonant strings and are asked to rate their 'goodness' (based on their first language), listeners use both statistical cues and stress cues to make their decisions. Thus, these cues seem to have an additive effect in the recognition and processing of spoken language. Interestingly, these cues seem to be relevant to listeners throughout their linguistic development. Additionally, this research suggests that words with primary stress are accessed more rapidly than unstressed syllables. These results seem to indicate that listeners use all cues available to them (statistical probabilities, phonotactic constraints, and stress patterns). Language is robust and, accordingly, language acquisition capitalizes on the multitude of cues.

Cognitive Approaches

Cognitive approaches to language acquisition deemphasize innate, domain-specific linguistic factors in favor of broader cognitive processes. The general assumption underlying these studies is that cognitive development serves as a prerequisite for language development. That is, children need to be able to understand a given concept before they are able to master its linguistic expression. Exploration of the relationships between cognitive and language development have occurred on several fronts.

One set of studies has examined language acquisition in children with cognitive disabilities. For example, research indicates that the language development of children with Down syndrome tends to be proportional to their cognitive deficits (Abbeduto et al., 2007): Children with more severe cognitive deficits typically experience more severe linguistic deficits. In contrast, some researchers have suggested that children with Williams syndrome, a disorder caused by the deletion of genes on chromosome 7, may have language abilities that are advanced relative to their cognitive development. Early work fit this pattern: children with Williams syndrome, although often experiencing significant cognitive delays, appeared to retain a higher level of linguistic skills, particularly syntactic skills. As a consequence, some scholars posited that these children possessed an innate language-specific domain.

More recent studies, however, suggest more proportionate linguistic deficits for these children (Mervis and Becerra, 2007). Current evidence is consistent with the notion that although children with Down and Williams syndromes have somewhat-different linguistic profiles – the former are weaker in syntax but stronger in vocabulary, whereas the latter are stronger in syntactic skills but weaker in visual-spatial abilities – both groups appear to experience delays in language development that are proportionate to their cognitive development.

Another line of inquiry has explored relationships between measures of cognitive development and various linguistic achievements. For example, some studies examined whether the achievement of object permanence, the awareness that objects continue to exist even if no longer present, precedes the acquisition of words such as *all gone* and *more* that may be used to encode that understanding. Research generally has found correlations between cognitive and language development. The evidence that cognitive achievements are necessary prerequisites for linguistic advances, however, is relatively weak: In some studies, cognitive milestones tend to cooccur with, rather than precede, linguistic achievements.

A third and perhaps more promising approach is represented by cross-linguistic studies. Johnston and Slobin (1979) found that the order in which children acquired locative expressions, such as *in*, *on*, *under*, *beside*, and *back*, was similar for children acquiring Italian, Serbo-Croatian, and Turkish, suggesting that the order of acquisition reflected the conceptual complexity of different spatial concepts. In contrast, other studies found that children acquiring Hebrew learn to form questions considerably earlier than children who are acquiring English. Presumably this disparity is related to the structural complexity of questions in English, which as already noted requires a number of linguistic operations. In contrast, in Hebrew, yes–no questions merely require speakers to use a rising intonation with declarative sentences.

Research studies suggest that cognitive development may serve as a general pacesetter for language development. It may be that cognitive achievements serve as a prerequisite for corresponding language achievements. Even so, language acquisition depends not only on cognitive readiness but also on the complexity of the forms that different languages use to encode particular concepts. It also may depend, as we have seen previously, on the frequency of exposure to particular linguistic items. Johnston and Slobin (1979) presented the metaphor of a waiting room as a way of expressing these relationships. Consider a room with an entry door and an exit door. The former represents the child's acquisition of certain cognitive prerequisites; this puts the child in the waiting room. Opening the exit door depends on other factors, such as the frequency of exposure to and the linguistic complexity of the item.

Conclusion

Although the modern study of language development began with nativist approaches, the field has moved away from strictly biological approaches in subsequent decades. Contemporary researchers, although acknowledging a biological component to language, have investigated how children might exploit the data typically presented to them in the course of language acquisition. Coupled with attention to children's cognitive readiness and the linguistic complexity of various aspects of language, studies of statistical learning may provide an important part of a more comprehensive account of language acquisition than is presently available.

At the same time, there has been a resurgence of interest in biological approaches. Two active areas of research pertain to mirror neurons and the FOXP2 gene. FOXP2 (Forkhead box protein P2) is the first gene to be identified as directly relevant to speech and language. Patients with an inherited genetic mutation of the FOXP2 gene show developmental verbal dyspraxia (difficulty producing the highly coordinated motor movements required by speech productions) and limited problems with language comprehension. In songbirds, a mutation of the FOXP2 gene results in reduced vocal learning. FOXP2 demonstrates that the ability to comprehend and produce language may be rooted in our evolutionary history.

Although FOXP2 likely is crucial to understanding the evolutionary development of language, mirror neurons focus are more immediately influential on individual language development. Mirror neurons are active when a person performs a behavior and when that behavior is observed in another individual. For example, mirror neurons in the motor cortex are active both when someone writes her name, as well as when she watches other people write their names. Currently, mirror neurons are known to influence imitation, action understanding, theory of mind, learning, and, of course, language. Although research on mirror neurons and linguistic processing is in its infancy, current hypotheses suggest that mirror neurons first facilitated communicative development in prelinguistic gestural communication. As humans' ability to communicate became more sophisticated, mirror neurons are thought to help grow vocabularies. For example, children's vocabulary increases with their ability to vocally mirror new words – a skill that some researchers link directly to mirror neuron activation. Mirror neurons may be an important beginning step in understanding the neural underpinnings of language development while also reinforcing the importance of social factors of language.

In many ways, biological theories of language acquisition are reminiscent of the early innate theories of linguistic development. Current biological theories, however, also stress the

importance of the linguistic environment. Thus, it appears that the development of language is not nature or nurture, but rather is a complex interaction of all the factors discussed in this article. Further advances in the theoretical explanation of language development continue apace. We can expect fuller examination of the interplay of cognitive, social, and learning abilities along with additional scrutiny of what newer biological approaches may convey.

Abstract

The course of linguistic development is shaped by processing pressures that reflect the interaction of internal factors such as burden on working memory with external factors relating to experience. Two case studies help reveal the central role of internal pressures in determining both the properties of language and the manner in which those properties emerge over time, opening the door to a new perspective on development.

Introduction

Much of the research program of contemporary linguistics focuses on two fundamental questions.

- Why do languages have the particular properties that they do?
- How do those properties emerge in the course of language acquisition?

Emergentism holds that the answer to both questions lies in the interaction of forces that exist independently of language. One such force, on which I will concentrate here, is processing cost.

The central thesis of this article is that processing pressures are largely responsible for the course of development – the series of changes that bring a learner's language in alignment with the language of his or her community. This idea can be stated informally as follows.

1. Processing determinism
   Processing pressures shape the course of development.

This thesis rules out the possibility that development is the product of maturational factors and/or environmental pressures unrelated to processing, but is neutral with respect to the nature of the mechanisms that emerge in the course of language acquisition. Although I take those mechanisms to be processing routines rather than conventional grammatical rules (e.g., O'Grady, 2005), nothing turns on that point here, and I will explore the consequences of processing determinism in theory-neutral terms to the extent possible.

Processing-related pressures come from two very different sources. On the one hand, there are external factors that arise from the environment, including the composition and quantity of the input to which learners are exposed. On the other hand, there are internal pressures that stem from the burden that particular linguistic phenomena place on working memory. I will consider each type of pressure in turn, before examining the question of whether development follows a uniform course despite apparent differences among individual learners.

External Pressures: The Role of Input

Most emergentist work on development maintains a strong input orientation. An early and very influential example of this comes from the classic Competition Model. Explicitly presented as a processing-based approach to development (MacWhinney, 1987: 301), the Competition Model focuses on the relative weighting of the input cues that help identify sound-meaning mappings. It makes a simple but daring prediction: by the virtue of its facilitatory effect on processing, cue validity should determine the order in which particular aspects of language are acquired (Bates and MacWhinney, 1987: 171).

In the classic model, cue validity reflects the interaction of two factors – availability (how often a cue is present in the input when a particular mapping is being computed) and reliability (how often the cue leads to the correct result). In English, for instance, the cue of noun–verb order, exemplified in (2), scores high in validity when it comes to identifying a sentence's subject.

2. Rob likes Lucy

Not only is noun–verb order almost always available in English (the vast majority of sentences have a noun to the left of the verb), it is also highly reliable (a preverbal noun almost always corresponds to the subject). In contrast, cues such as case (*he* vs *him*, *she* vs *her*) or verbal agreement are less frequently available, and are hence less valid. These facts are reflected in development in the predicted way: children learning English initially rely primarily on word order to distinguish subjects from direct objects. In other languages, of course, other cues have a higher validity (e.g., animacy in Italian, and case in Turkish), shaping development in those languages accordingly (Slobin and Bever, 1982; Bates et al., 1984).

The Competition Model is just one of several streams of emergentist thought that focus on the role of input in shaping development. Usage-based and constructivist approaches to language acquisition (e.g., Tomasello, 2003; Goldberg, 2006;

MacWhinney, 2010; Ambridge and Lieven, in press) place special emphasis on children's pattern-finding skills. Research on statistical learning (Saffran et al., 1996, 2008; Thompson and Newport, 2007) focuses on learners' ability to track transitional probabilities (the likelihood that the occurrence of X will result in the appearance of Y), a phenomenon that is also the object of connectionist modeling (Elman, 2002; Chater and Manning, 2006; Chang et al., 2006). Dynamic Systems Theory (van Geert and Verspoor, in press) investigates linguistic development by considering how proficiency changes over time in response to the interaction of experience, maturation, and previous learning.

It makes sense to expect input to have a major role in shaping development. All other things being equal, frequent sound-meaning mappings should emerge and become entrenched before their less frequent counterparts. And this is in fact more or less what happens (Menn, 2000; Jurafsky, 2003; Ferreira, 2003); for a general review, see Jaeger and Tily (2011).

However, processing pressures that come from the input tell only part of the story. There is also a network of internal efficiency-related processing considerations that help to shape development in significant ways, alone and in conjunction with input. Unfortunately, the effect of these factors is often difficult to discern because of the presence of parallel external pressures. The development of relative clauses is a case in point.

A frequent finding in the acquisition literature is that children learning English find subject relative clauses easier to produce and understand than direct object relative clauses (Diessel and Tomasello, 2005; Friedmann et al., 2009; O'Grady, 2011).

3a. Subject relative clause:
the boy [that _ hugged the girl]

3b. Direct object relative clause:
the boy [that the girl hugged _]

There are a number of promising processing accounts for this asymmetry. For example, Grodner and Gibson (2005) propose that processing cost is determined, at least in part, by the amount and type of material intervening between the gap inside the relative clause and the associated 'filler' (*the boy* in our examples). The sole intervening element in the subject relative clause in (3a) is the complementizer *that*. In the direct object relative clause in (3b), in contrast, two major constituents (the NP *the girl* and the verb *hug*) intervene between the filler and the gap – increasing the burden on working memory and contributing to later mastery.

Unfortunately, however, the force of this explanation is somewhat compromised by a possible frequency-related input effect. At least some corpus research reports that subject relative clauses are in general more frequent than direct object relative clauses, and the asymmetry is overwhelming when one takes into account animacy: relative clauses that modify an animate noun, such as those in (3), are far more likely to be of the subject type than the object type (e.g., Kidd et al., 2007). Thus input factors too could be responsible for the early mastery of subject relative clauses.

Confounds between internal processing cost and frequency of occurrence in the input are to be expected: all other things being equal, language use should favor patterns that incur less processing cost. How then can we ensure that processing determinism in development is not simply input determinism?

The Case for Internal Factors

The key to establishing an independent role for internal processing factors lies in showing they have effects distinct from those predicted by external factors. Various phenomena offer the opportunity to pursue this line of inquiry, and I will consider two such cases here, both involving comprehension. In this regard, I depart from the practice, common in much of the literature on development, of focusing just on production. This departure is justified for two reasons.

First, advances in comprehension drive language acquisition. Without the input that comes from understanding the linguistic patterns that are exemplified in the speech of others, there would be no development. Moreover, development is possible in the absence of production, as the investigation of mutism has documented (Lenneberg, 1962; Hickok, 2009).

Second, as I will try to demonstrate in what follows, key insights into the nature of development come from the study of patterns for which there are few opportunities for use, especially in the speech of children. An exclusive focus on production in such cases would exclude them from consideration, an obviously undesirable result.

Scope Preferences in First Language Learners of English and Korean

A signature feature of natural language is its capacity for the expression of negation and quantification. The sentence in (4) offers a simple example.

4. Kim didn't buy all the pencils.

The dominant interpretation of this sentence is that Kim bought only some of the pencils (the so-called '*not* > *all* reading'), not that no pencils were purchased by Kim (the '*all* > *not* reading'). Interestingly, the reverse is true in Korean (Subj = subject marker; DO = direct object marker; Pst = past tense; Decl = declarative).

5. Kim-i motun yenphil-ul an sa-ss-ta.
Kim-Subj all pencil-DO not buy-Pst-Decl
'Kim bought none of the pencils.' (All the pencils went unpurchased.)

Very few sentences containing a negated verb and a universally quantified direct object occur in parental speech in either Korean or English (O'Grady, 2013). Yet scopal interpretations appear to develop in a systematic way, following a particular (but different) course in each language. Whereas Korean-speaking children manifest a strong preference for the *all* > *not* interpretation from the outset (Han et al., 2007), English-speaking children initially permit both the *all* > *not* and the *not* > *all* interpretations (Musolino et al., 2000; Musolino and Lidz, 2006).

As I have argued elsewhere (e.g., O'Grady, 2013), processing pressures offer an explanation for both why Korean and English differ in their scopal preferences and why the emergence of those preferences follows a different path in each language. Let us first consider the case of Korean.

The two key steps in processing the Korean scopal pattern can be schematically depicted as follows. (The symbol ∀ stands for universal quantification, and the symbol ¬ for negation.)

6a. Step 1: The processor encounters the quantified NP.
Kim all the pencils ….
∀x (pencils)

6b. Step 2: The processor encounters the negative.
Kim all the pencils not buy
∀x (pencils) ¬ → *all* > *not*

As illustrated here, the quantified NP is encountered and interpreted early in the sentence (step 1). This leaves just one option at the point at which the processor comes upon the negative: the *all* > *not* interpretation, as shown in (6b). Derivation of the alternative *not* > *all* option can be achieved only through revision of that initial interpretation, as depicted below.

7. Kim all the pencils not buy
∀x (pencil) ¬→ *all* > *not* (first interpr.) → *not* > *all* (revised interpr.)

It seems reasonable to suppose that revisions to a previously derived interpretation are costly (O'Grady 2013 and the references cited there) – hence children's avoidance of this option in Korean.

Matters are very different in English. Because the negative precedes the quantifier, the processor comes upon it first and registers its presence in the sentence.

8. Step 1: The processor encounters the negative.
Kim didn't buy
¬

Upon subsequently encountering the quantified NP, the processor has two options: allow the negative to scope over the quantifier (the *not* > *all* interpretation) or avoid any such interaction (the *all* > *not* interpretation).

9. Step 2: The processor encounters the quantified NP and computes scope.
Kim didn't buy all the pencils
¬ ∀x (pencils) → *not* > *all*
→ *all* > *not*

Because there are no grounds for believing that either option is inherently more costly, neither should be favored in the absence of relevant input. As summarized in **Table 1**, this aligns exactly with the initial state of development for English, which is characterized by acceptance of both interpretations.

In sum, processing pressures offer a straightforward explanation both for the difference in scopal preferences exhibited by Korean and English and for the developmental profile seen in each language. The reason that Korean strongly favors the *all* > *not* interpretation and the reason that children initially seize on that option is that it has a lower processing cost than its *not* > *all* counterpart. And the reason that English is not constrained in this way and that children initially allow both the *not* > *all* and the *all* > *not* interpretations is that the two options are comparable in processing cost.

Table 1 The developmental sequences for scope in English and Korean

English	*Korean*
1. Both *not* > *all* & *all* > *not* accepted 2. Strong preference for *not* > *all*	1. Strong preference for *all* > *not* 2. No change

Table 2 Developmental sequences for reflexive and plain pronouns

Reflexive pronouns	*Plain pronouns*
1. Correct interpretation	1. Possible misinterpretation as a reflexive 2. Correct interpretation

Of course, this does not mean that there is no role for input. Somehow, English speakers later come to favor the *not* > *all* interpretation, presumably on the basis of experience, however sparse, that is accumulated over a period of many years. (Recall that the preference is not manifested in the judgments of school-age children.) This fits well with the idea that the course of development is shaped by a combination of internal and external processing factors.

Reflexive Pronouns

Children learning English manifest a curious asymmetry in their interpretation of pronouns, with higher early success on reflexive pronouns (*himself*, *herself*, etc.) than on their plain counterparts (*him*, *her*, etc.). Of particular interest is the type of error most commonly made: plain pronouns are misinterpreted as reflexive pronouns, but not vice versa (Conroy et al., 2009; O'Grady, in press; **Table 2**).

Frequency of occurrence offers no explanation for this asymmetry, as plain pronouns occur far more commonly than their reflexive counterparts in caregiver input. In a search of the Child Language Data Exchange System (CHILDES) database, I uncovered 1836 instances of *him*, *her*, and *them* in maternal speech to Adam, Eve, and Sarah, compared with just 17 instances of *himself*, *herself*, and *themselves*.

In contrast, processing pressures offer a compelling explanation for the developmental facts, as the two types of pronoun differ in terms of the resources needed to locate the appropriate antecedent. As is standardly observed, reflexive pronouns typically require a 'local' antecedent – almost always an argument in the same clause, as illustrated in (10).

10. [**Mickey** tickled **himself**].
↑_____|

In contrast, the search for an antecedent in the case of plain pronouns focuses on referents that are prominent in the discourse, without regard for locality (Song and Fisher, 2007; Foraker and McElree, 2007; among many others).

11. Mickey tickled **him**
↖_____|

As frequently noted (e.g., Reinhart, 2006: 181ff; Reuland, 2011: 127), a search through discourse often involves greater processing cost than is required for the interpretation of a reflexive pronoun, whose antecedent is predictably located in the same clause.

Internal processing pressures thus provide a straightforward explanation for children's difficulty with plain pronouns, even after exposure to ample input. Of course, this does not mean that there is no role for experience – after all, the right forms have to be learned (*himself* rather *hisself*, *myself* rather than *meself*). In the important matter of interpretation, however, internal processing pressures do the heavy lifting.

Summary

The two case studies that we have been considering are instructive for two reasons. First, from the point of view of typology, they illustrate how processing pressure can shed light on why languages have the particular properties that they do. Korean favors the *all* > *not* interpretation of scopal patterns because that reading is easier to process than the alternative. English, like countless other languages, requires local antecedents for reflexive pronouns because that interpretation minimizes the processing cost associated with resolving referential dependencies and so on.

Second, the same processing forces that favor patterns of a particular type shape the emergence of language in children, establishing the course of early development. In some cases (perhaps relative clauses), internal processing pressures act in conjunction with the input, but there are also telling cases in which they act on their own, neutralizing the potential influence of input (as in the case of pronoun interpretation) and even making up for the absence of relevant experience (as in the case of scopal patterns).

How Uniform Is Development?

Although it is sometimes suggested that development is highly uniform (e.g., Brown, 1973; Pienemann, 2005), much recent work points in the opposite direction. Dynamic Systems Theory, in particular, has emphasized both intralearner variability and interlearner variation, raising the possibility that no two learners proceed at the same rate, make the same errors, or attain proficiency in the same manner (de Bot et al., 2007; van Dijk et al., 2011; Verspoor and van Dijk, 2011). What is the reality?

There is some reason to think that developmental diversity, however widespread, is circumscribed by the influence of processing pressures.

12. The Uniformity Thesis
    Development is uniform, where processing cost is relevant.

Three points call for immediate clarification.

First, the Uniformity Thesis has nothing to say about differences in *rate* of development – a well established and well documented parameter of ontogenetic variation. The cost of maintaining and accessing a vocabulary of, say, 150 words is the same, regardless of whether those words are acquired by age 18 months or by age 24 months. The cost of computing the agreement relationship between a verb and subject (*A boy is/*are outside*) is the same when acquired at 30 months as it is when learned at 36 months. These and other differences unrelated to processing cost fall outside the scope of processing determinism (and, by extension, the Uniformity Thesis).

Second, a large portion of the variation across learners that is reported in the literature arguably reflects differences in language use that are present independent of development. This is especially so in the case of spontaneous speech – a very common source of data in studies of developmental order (Brown, 1973; Pienemann, 2005; Bassano and van Geert, 2007). Even mature monolingual speakers of a language differ in their ability to express themselves in extemporaneous speech, and there can be fluctuations in performance literally from moment to moment. Variation and instability are no doubt magnified in learners, whose processing routines are less entrenched than those of mature speakers and hence even more susceptible to the factors that make speech difficult in the first place. Conclusions based on production data therefore need to be interpreted cautiously, and tempered by the insights afforded by controlled experiments, including those involving comprehension.

Third, the Uniformity Thesis does not predict that learners will follow identical paths of development regardless of input; rather, it predicts uniformity in the effect of input. An obvious case in point involves lexical development, whose precise course varies considerably from child to child, but nonetheless appears to reflect experience quite faithfully (Huttenlocher et al., 1991; Hoff and Naigles, 2002). That is why, to take a trivial example, children growing up in America learn the words *truck*, *elevator*, *cookie*, and *apartment* before *lorry*, *lift*, *biscuit*, and *flat*, whereas the reverse is true for children growing up in the United Kingdom.

The study of morphosyntax offers comparable examples. It would not be surprising to find earlier emergence of *shall* in the United Kingdom than in the United States, or a preference for *I don't have any milk* over *I haven't any milk* in American children but not in their British counterparts. In these and other cases, development is presumably as uniform as the input that drives it.

If all of this is right, then the case for Uniformity depends crucially on the effect of internal processing factors, especially those that operate without the confounding influence of input. Do such factors shape development in a uniform way across children and even across languages? If the phenomena considered in this article are typical, the answer may well be yes.

- Children learning Korean uniformly show an early preference for *all* > *not* scope. In contrast, English-speaking children initially permit either interpretation.
- English-speaking children sometimes interpret plain pronouns as if they were reflexives (e.g., Conroy et al., 2009), but errors in the reverse direction are uniformly avoided.

Findings of this sort point toward a fundamental similarity in those aspects of development that are shaped by internal processing pressures, consistent with the Uniformity Thesis.

Conclusion

Development is a signature phenomenon of language, and its study offers the promise of insights into the mechanisms that make language possible in the first place. The emergentist approach to this challenge takes as its starting point the idea that processing cost shapes both the properties of language and the manner in which those properties are acquired. A key component of the particular proposal that I have put forward is a distinction between two quite different determinants of processing cost, one rooted in internal pressures relating to burden on working memory and the other reflecting the composition and quantity of learners' experience. The two case studies considered here point to the crucial role of internal factors in shaping the emergence of language, at times in the absence of relevant input. Moreover, these studies raise the possibility that development may unfold in a more uniform manner than is usually assumed. For now, though, these conclusions remain tentative, awaiting the further work that is needed to fully assess their viability.

Language Development: Evolutionary Theories

Mark Atkinson and Kenny Smith, Language Evolution and Computation Research Unit, School of Philosophy, Psychology and Language Sciences, University of Edinburgh, Edinburgh, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Accounts of language development can be broadly divided into two opposing camps: nativist theories and statistical learning accounts. We review the claims made by each about the role of the socially acquired linguistic data in language acquisition and consider the implications of each account on the likely evolutionary history of the language-learning capacity.

Our species is characterized by a uniquely powerful communication system: anything we can think, we can convey to others using language. No other species has a communication system that comes close to offering this level of expressive power; instead every other system is limited to the communication of a small number of possible messages on a tightly circumscribed set of topics (e.g., sources of dangers, sources of food, or availability as a mate). Human language is also relatively rare in that it is learned (see Fitch, 2000, for a discussion of the scarcity of learned communication in the natural world): we acquire the language of our speech community based on exposure to the linguistic behavior of that community. Explaining the evolution of language therefore amounts to explaining the evolution of the uniquely human capacity to acquire a language from linguistic data. So how did the capacity for this unique communication system evolve in our species and why is it not more widespread in the natural world?

Accounts of language development can be broadly divided into two opposing camps: nativist theories, emphasizing the role of innate, domain-specific knowledge relating only to language, and statistical learning accounts, emphasizing the richness of linguistic data and the role of domain-general learning procedures. Both views of language development accept that socially provided language input is necessary, but the function of this input in each account is very different: in nativist accounts its role is merely to activate the linguistic knowledge already present within an individual learner; in statistical learning accounts it is the sole source of linguistic knowledge. These two views of language learning also make very different claims about the likely evolutionary history of the language-learning capacity, which we review here.

Nativism and the Evolution of Language Learning

Nativist accounts of language acquisition date back to the late 1950s and are mostly associated with the theories of Noam Chomsky (e.g., Chomsky, 1965). Nativist theories seek to explain how children acquire the formal rules describing a language's grammar from linguistic input which is, they argue, deficient in a number of crucial ways (*see* Language Acquisition). In particular, the data provided to children as input forms but a small sample of the infinitely many possible sentences which could be produced by a language that is capable of being infinitely expressive. Furthermore, certain grammatical structures are argued to be unlearnable without 'negative evidence,' explicit, impermissible counterexamples to grammatically well-formed sentences. The solution to this problem of acquiring a language from degenerate data is the proposed existence of 'Universal Grammar,' UG. UG is an innate, genetically encoded module that provides the complex, abstract and formal knowledge necessary to acquire the grammatical system of any language. Acquiring a language then requires very little learning, if indeed 'learning' is thought to happen at all (Piattelli-Palmarini, 1989). In addition to providing elements such as a language's lexicon (considered a relatively superficial aspect of the language-learning problem), the linguistic input simply serves to guide the child to a particular grammar from within the set of possibilities defined by UG (*see* Language Development, Theories of). Under one influential account (Chomsky, 1981), this is achieved through the setting of a small number of 'parameters,' each of which specify one or more structural properties of a language and can be set using relatively simplistic linguistic data, the trigger for setting that parameter. This process has been likened to the setting of a number of 'switches' within the 'switch box' provided by UG. For instance, one parameter might determine whether a language has a fixed or free word order, with its setting dependent on whether the input received is from a language with more rigid ordering of words in its sentences, such as English, or a syntactically more flexible language, such as Hungarian. UG therefore defines a space of possible human language types, one for each possible combination of parameters: in principle, it might be possible to determine the parameters of UG by inspecting the range of languages we see in the world and how they vary (Baker, 2001), since this variation should by definition be constrained by UG. 'Linguistic universals,' ubiquitous features thought to exist in all natural languages, are therefore a result of genetically encoded constraints on possible languages within the individual.

Where did UG, this rich, complex, species-wide biological capacity, come from? The definitive argument for UG as a product of evolution by natural selection is provided by Pinker and Bloom (1990), who argue that such a trait can only be explained as the result of an adaptionist process, as:

> The only successful account of the origin of [any] complex biological structure is the theory of natural selection.
>
> Pinker and Bloom, 1990: p. 708

In their theory, the uniquely social ecology of humans puts a premium on the ability to communicate knowledge and internal states to others. Language provides the apparatus to do this (*see* Biological Preconditions for Language Development), and individuals whose genes equip them with the ability to learn a complex system for expressing such knowledge using language, and understanding others when they do so, will be at a selective advantage: thanks to the many benefits of sharing hard-won knowledge with friends and family, such individuals will be more likely to survive and reproduce, leading to the gradual evolution of the modern language faculty. Pinker and Bloom identify a number of features of language which, they argue, exhibit the appearance of design for this function. For example, they argue that major lexical categories (such as nouns and verbs) are used to distinguish basic ontological categories, phrase structure and overt case marking provide surface cues to the structure of the underlying propositions which language is used to convey (i.e., who did what to who), and verb affixes signal temporal aspects of events (whether it happened in the past, will happen in the future, or is happening now). Pinker and Bloom go on to identify scenarios where language exhibiting these design features might offer a selective advantage. They propose that the hunter-gatherer lifestyle hypothesized to characterize our recent evolutionary predecessors would favor an ability to communicate information about toolmaking, ecology, and the behavior of plants and animals:

> Devices for communicating precise information about time, space, predicate–argument relations, restrictive modification, and modality are not wasted in such efforts.
>
> Pinker and Bloom, 1990: p. 724

Secondly, they emphasize the value of language in supporting social interactions, which put

> a premium on the ability to convey such socially relevant abstract information as time, possession, beliefs, desires, tendencies, obligations, truth, probability, hypotheticals, and counterfactuals… Furthermore, in a group of communicators competing for attention there is a premium on the ability to engage, interest and persuade listeners. This in turn encourages the development of discourse and rhetorical skills and the pragmatically relevant grammatical devices that support them.
>
> Pinker and Bloom, 1990: p. 725

Therefore, according to Pinker and Bloom, the human capacity to acquire complex language evolved as a direct consequence of the payoff it provided in relation to these communicative functions. As clarified in Pinker (2010), this adaptive account of the evolution of the human capacity to learn language fits within the broader explanatory framework of evolutionary psychology (and indeed has been hailed as the crowning success of that school of thought by Tooby et al., 2005): the capacity for language is only one of a suite of cognitive adaptations arising from the human cognitive niche, characterized by our social interdependence and reliance on knowledge acquired from others (*see* Human Language, Evolution of).

Why, under this account, does UG also constrain the kinds of languages that can be learned? According to Pinker and Bloom, the evolutionary drive for expressive power was tempered by the requirement for speaker–hearer parity. Any arbitrary communication system would have been advantageous, but it would have been necessary for it to be conventionalized; that is, shared among the members of a group. Individual elements of such a system would originally have to be learned, but once conventionalized, might gradually become innate (i.e., hardwired into individuals) due to the 'Baldwin effect': the increased genetic coding of advantageous acquired traits over a large number of generations (Baldwin, 1896). Nativization of conventional aspects of language structure removes the risk of failing to learn and paves the way for innate constraints on language learning as found in UG.

This adaptationist account of the evolution of UG has received support from models of the evolution of communication systems, most notably from Martin Nowak and colleagues (Nowak et al., 1999, 2000, 2001), who present a series of models exploring the conditions under which grammatical language and UG might evolve under natural selection. Nowak et al. (2000) compare the fitnesses of individuals pursuing two possible learning strategies: holistic learners, who learn unitary agrammatical utterances to describe complex events, and compositional learners, who learn a system of labels for the component parts of complex events (e.g., individual words for objects and actions) and describe complex events using combinations of those simpler labels. They then calculate the number of labels that can be sustained in a population of such learners (which is dependent on the accuracy of learning) and the probability of successful communication between two individuals drawn from such a population (i.e., the probability that, for a given event, both individuals will know the word or words required to describe that event). Using this approach, they are able to show that the compositional learning strategy will be selected for (i.e., will lead to more successful communication) whenever the total number of complex events to be communicated about exceeds a certain threshold size: when there is a small number of events to be labeled (and/or words in a compositional system are harder to learn than unitary utterances), it pays to have a nongrammatical, holistic system of communication. On the other hand, if the number of events to be communicated about is large, then holistic systems become unwieldy (you are unlikely to have encountered the labels for every event) and the possibility of generalization afforded by the compositional strategy pays off: while it is unlikely that you and your communicative partner have heard precisely this complex event described before, you probably know the words for describing the component parts and can therefore successfully communicate anyway. While this model is extremely simple, it confirms the central intuition behind Pinker and Bloom's paper, namely that the large set of things that humans need to talk about will lead to evolutionary pressure in favor of learners who can acquire a rule-based system for expressing those concepts, that is, a compositional language.

Nowak et al. (2001) then consider the evolution of a restrictive UG, of the sort discussed above, which constrains learners to considering a relatively small set of possible languages (perhaps characterized by a small set of parameters).

They provide two general results. Firstly, there is selection in favor of a language faculty which reduces the size of the search space to levels that allow a population to converge on a shared grammar, as predicted by Pinker and Bloom (1990): if the space of possible languages considered by learners is very large, members of a population may end up arriving at different grammars on the basis of the same linguistic data and therefore fail to communicate; this can be avoided by reducing the size of the space of possible languages to below the 'coherence threshold,' which allows a population to reliably converge on a shared language. However, this selection in favor of a constrained UG has its limits, and will not lead to the most constrained possible learner: once the space of possible grammars has been reduced sufficiently to meet the coherence threshold, there is selection against being overly constrained. Essentially, there is an advantage to remaining flexible: an overly constrained learner risks being born into a population of less-constrained learners who use a language which the more constrained learner cannot acquire. Nowak et al. (2001) conclude that this balance of selective pressures will lead to learners whose UG is constrained enough to permit convergence within a population, but which is nevertheless permissive, allowing them to learn the largest possible set of languages within the limits of convergence. This result matches the prediction provided by Pinker and Bloom: constraints on language learning facilitate communication, at least up to a point.

Criticisms of the Adaptationist Account

Perhaps surprisingly, the adaptationist account of the evolution of UG has been criticized from within the nativist camp: most notably, Noam Chomsky, the founder of the theory of UG, has been notoriously reluctant to offer an account of the origins of this innate and language-specific organ of the human mind, preferring instead to offload the explanatory burden on the notion of inherent constraints on the nature of computation:

> Language is clearly a computational system. Therefore, it makes sense to seek the role of general principles of computational efficiency that apply far more broadly and may well be rooted in organism-independent natural law. This is particularly natural given the very little we know about the evolution of language. When a generative process (GP) emerged in some individual, perhaps by some slight rewiring of the brain, it should have been as simple as possible, the minimal change from the earlier state, presumably by mutation. Furthermore, there were no selectional pressures at that initial stage, so we should therefore expect the emergent GP to be determined solely by natural law.
>
> Chomsky, 2011: p. 271

Other work that takes evolutionary theory more seriously has identified potential problems with the evolutionary account put forward by Pinker and Bloom (1990). In a series of articles (e.g., Christiansen and Chater, 2008; Chater et al., 2009), Christiansen and Chater outline what they see as two key problems with the adaptationist account. Firstly, nativist accounts assume that UG is shared across our species, as the 'Universal' in 'Universal Grammar' would suggest, and as the ability of any child to acquire any human language seems to testify. Given that our species began dispersing across the planet 100 000 years ago, with concomitant diversification of the languages of those populations, they question why the same evolutionary mechanisms which lead to the development of UG would not continue to operate postdispersion, fine-tuning the 'U'G of each population to specialize in the acquisition of the languages of that region. While some accounts do suggest that there might indeed be subtle variations in the ability to acquire linguistic features (Dediu and Ladd, 2007), there is as yet no evidence for substantial geographic differences in the ability to acquire languages that might be predicted under this kind of theory. Secondly, Chater et al. (2009) use a computational model to demonstrate that biological evolution cannot encode innate constraints for linguistic features that change rapidly as a result of external factors (e.g., language contact): the Baldwin effect requires a reasonably stable target of assimilation; however, languages change fast, too fast to allow the Baldwin effect to operate.

However, much of the opposition to adaptationist accounts arises not from the internal logic of their account, but the rejection of their premise that language is fundamentally a biological capacity, that language learning is necessarily under strong innate constraints, and that the data a learner receives is deficient. It is to these alternative accounts that we now turn.

Statistical Learning and the Evolution of Learnability

Alternatives to the nativist accounts of language development focus on the human capacity for statistical learning, and make very different claims about the evolution of the human capacity to learn language. Statistical learning refers to the process of acquiring information about the environment – in this case, the linguistic environment – by identifying rules and statistical regularities in a rich sample of data provided by that environment. For language, this involves identifying features such as phonemes, syllables, word meanings, lexical categories, and syntax from the kinds of rich, raw linguistic data that children are exposed to (Romberg and Saffran, 2010; Rebuschat and Williams, 2012). Importantly, language learning is assumed to be possible without abstract innate knowledge of the learning task: rather, learning involves the application of domain-general learning procedures to multiple domains (see Saffran and Thiessen, 2007, for a review).

If language acquisition is a result of the application of domain-general learning processes that apply to learning about many aspects of the world (e.g., the social and physical environment) as well as language, then what can be said about the evolution of the human capacity to learn language? Under statistical learning accounts, language learning is not a separate capacity in need of a unique explanation: humans are unusual in the extent and ubiquity of their reliance on learned behaviors in many domains, and in particular on socially learned behaviors (behaviors that are learned from others). The challenge then becomes to explain why humans rely so much on (social) learning in general, including the social learning of their communication system. When framed

like this, the evolutionary account implicit in statistical learning seems quite close to the notion of a uniquely human cognitive niche proposed by Pinker (2010), but assumes that the human adaptation to this cognitive niche is a unique propensity for sophisticated social learning, rather than a suite of independent, domain-specific modular adaptations. Indeed, we may be able to gain an insight into the ancient roots of the human capacity for statistical learning by adapting techniques from comparative psychology, studying homologous statistical learning capabilities in other species, including other primates (Fitch and Hauser, 2004), rodents (Toro and Trobalon, 2005), and birds (Stobbe et al., 2012) (*see* Human Language: Evolutionary Precursors). Such an approach, in determining which elements of our capacity for language we share with other species and which are uniquely human, may also go some way to reconciling statistical learning accounts of the evolution of language development with nativist ones (Hauser et al., 2002).

Statistical learning accounts therefore assume that one of the key motivations for nativist accounts of language learning – the notion that language acquisition is easy, but would be impossible without innate knowledge of how languages work – is based on a failure to appreciate the power of domain-general statistical learning techniques. A recent strand of work also explores how the socially learned nature of language offers another potential solution to the 'mystery of fit' between language and language learners (Christiansen and Chater, 2008): rather than language learners adapting themselves to the challenge of language acquisition, languages adapt to suit their learners, minimizing the challenge of language acquisition. Languages persist by a process of cultural transmission (*see* First Language Acquisition, Developmental Psychology of), with the linguistic output of one generation forming the input for social learning in the next (*see* Evolution and Language: Cultural Transmission). Because language is transmitted in this way, language learners can have a direct influence on the structure of the language that subsequent generations of learners must learn, because that language passes through them:

> The structure of a language is under intense selection because in its reproduction from generation to generation, it must pass through a narrow bottleneck: children's minds… Language operations that can be learned quickly and easily by children will tend to get passed on to the next generation more effectively and intact than those that are difficult to learn. So, languages should change through history in ways that tend to conform to children's expectations.
>
> Deacon, 1997: p. 110

As a result of this process of filtering through the minds of language learners, languages will gradually evolve to reflect the biases inherent in language learning. Consequently, individual language learners are only faced with acquiring languages which have already been shaped for learning by previous generations:

> Human children appear preadapted to guess the rules of syntax correctly, precisely because languages evolve so as to embody in their syntax the most frequently guessed patterns.
>
> Deacon, 1997: p. 122

This pressure arising from repeated learning can also explain the presence of grammatical rules of the sort that Nowak et al. (2000) sought to explain by appealing to natural selection: the central observation by Nowak et al. that compositional linguistic rules facilitate generalization also means such rules are favored during language transmission, as they allow the learner to recover the language of the previous generation from limited data (Kirby, 2001; Zuidema, 2003; Brighton et al., 2005).

In addition to these pressures arising from learnability, language use will also leave its imprint on language design (Christiansen and Chater, 2008), as languages will also be subject to pressures resulting from both the language users' need for expressivity and preference for minimal processing costs (Kirby, 1999). Languages are so well designed for communication not because of the biological evolution of the language faculty under natural selection, but because of the accumulation of modifications made by people using language to communicate, which then show up in the linguistic data subsequent learners acquire their language from. Again, this is closely related to Pinker and Bloom's idea that language is adapted for communication: the only difference is the mechanism driving adaptation is the cultural evolution of languages themselves, rather than the adaptation of the language faculty on a biological timescale.

This account of language development, and its explanation of how languages adapt to their learners and users, also makes very different claims about the languages we would expect to observe around the world and any commonalities they share. Nativist accounts describe a comparatively transparent relationship between the parameter settings in individuals and the structural features of the languages they speak, and between the constraints of UG and linguistic universals. Statistical learning accounts, however, predict a more complex link between learner and language. As weak biases of learners can ultimately have strong effects on a language as it is repeatedly transmitted from generation to generation (see Smith, 2011, for review), a language universal may reflect an amplification of these weak, underlying biases rather than any absolute constraint on a language learner. There should therefore be very many more learnable, usable languages than those we can observe in the world now, and so the current typological distribution of world languages may only be a small subset of all plausible languages.

The relationship between the biases of individual language learners and the features of languages is also thought to be further obscured by mediating sociocultural factors, such as the number of users of a language, the complexity of a speech community's social structure, and the proportion of users who speak it as a second language, all thought to influence its linguistic characteristics. For example, a larger number of speakers of a language is proposed to result in the selection of more 'simple' grammatical features, such as more regular tense marking or lexical, rather than morphological, case marking, as the language is transmitted across generations (e.g., Dale and Lupyan, 2012; Nettle, 2012).

Conclusion

Humans have a unique capacity to acquire complex, expressive, grammatical language. This capacity must have some basis in

uniquely human biology, but precisely what this biological contribution is remains open for debate. We have reviewed two possibilities here. The capacity to acquire language may be an adaptation, a domain-specific component of the human mind evolved under natural selection due to the communicative payoff associated with the ability to learn language. Alternatively, languages themselves might evolve as they are passed from person to person, with language acquisition being the result of the application of less specialized, domain-general learning procedures. The resolution of this debate will depend in part on further painstaking exploration of the processes of language development in individuals, the evolutionary dynamics arising from the complex interplay between the biological and cultural processes that shape language, and the comparative psychology of statistical learning. In both cases, the evolution of the human capacity to acquire language is likely an evolutionary consequence of the uniquely social human ecology, characterized by the exchange of knowledge between individuals via language and social learning.

Language Development: Influence of Socio-Economic Status

Erika Hoff and Krystal M Ribot, Florida Atlantic University, Davie, FL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Family socioeconomic status (SES) is related to language development in multiple domains, throughout childhood, and in adulthood as well. Children from lower SES homes show lower levels of language and communicative skill than children from higher SES homes beginning in infancy. The gap between lower and higher SES children persists and sometimes widens with age. Substantial evidence locates the source of these differences in children's language experience. Children from lower SES homes are talked to less, and the speech they hear is less supportive of language development. The evidence that SES-related differences in parents' speech cause SES-related differences in children's language development is consistent with theoretical approaches that give experience an important role in the language acquisition process.

The goal of this article is to summarize the evidence that socioeconomic status (SES) is related to language development and to review the literature that explains why SES has this effect. Family SES is a powerful predictor of many aspects of child development and, relatedly, of many aspects of parenting behavior (Hoff et al., 2002; Keating and Hertzman, 1999; Linver et al., 2002; National Research Council and Institute of Medicine, 2000). This article focuses on the relation of SES to children's language development and to the antecedent SES-related differences in how parents use language in interaction with their children. The first section of this article provides a definition of SES. The second and third sections review the evidence that SES influences children's language acquisition and does so via the influence of SES-related differences in the speech adults address to children. A final section considers the theoretical implications of the observed relations among SES, language experience, and language development.

Definitions of Socioeconomic Status

SES refers to an individual's or household's relative position in a social hierarchy. Traditionally, this hierarchy has been defined in terms of access to, or control over, wealth, prestige, and power (Mueller and Parcel, 1981). More recently, SES has been conceptualized in terms of three sorts of capital or resources that families have access to: financial capital (material resources), human capital (nonmaterial resources, such as knowledge and skills), and social capital (connections to a larger social group) (Coleman, 1988). Researchers have measured SES using indicators of parents' level of education, household income, and prestige of occupation, or using a composite index based on multiple indicators (Hoff et al., 2012). Each component of SES may be associated with some level of risk for poor developmental outcomes because both US and international data suggest that greater disparities and/or greater predictive power are associated with the use of multiple indicators (Fernald et al., 2011; Halle et al., 2009). Often, however, research has used maternal education as the sole index of SES on the logic that education is highly correlated with other measures, is stable, and appears to be the best single predictor of child outcomes (Hoff et al., 2012). Furthermore, some research indicates that outside of extreme poverty, maternal education is the component of SES most strongly related to parenting measures (Bornstein et al., 2003; Hoff et al., 2002).

Relations between SES and Language Development

Throughout childhood, higher SES children have more advanced language skills than lower SES children of the same age. SES-related differences in children's communicative behavior have been found as early as infancy, are consistently found in the preschool and school-age years, and appear in adulthood as well. For instance, Halle et al.'s (2009) study of a nationally representative sample of approximately 11 000 infants born in the United States in 2001 found SES disparities in language skills (e.g., expressive vocalization and naming objects) in infants as early as 9 months of age, and the SES-related disparities widen by 24 months of age (e.g., in receptive and expressive vocabulary and listening/comprehension). In a public school sample, Oller and Eilers (2002) found SES-related differences in kindergarten and 5th grade children's scores on standardized tests of oral vocabulary equal to almost one standard deviation. Among adults, Hoff-Ginsberg (1991) found that education level was related to the amount of speech, the lexical richness, and the syntactic complexity of utterances that mothers addressed to an interviewer, and Van den Broeck (1977) found education level was related to the syntactic complexity of the speech used by adults in conversation.

SES-related differences in children's language skill have been observed across multiple domains of language including vocabulary, grammar, communication, narrative skill, phonological awareness, and processing speed.

SES Differences in Vocabulary

A difference in vocabulary size is the most reliably observed SES-related difference in language skill. A vocabulary gap has been found as early as the toddler years (Halle et al., 2009; Hart and Risley, 1995). The gap further widens by age 4 and then

remains fairly stable through the school years (Farkas and Beron, 2004). The magnitude of differences related to SES can be large. Hart and Risley (1995) found that by 3 years of age, the mean cumulative recorded vocabulary for the higher SES children in that sample was over 1000 words while for the lower SES children it was close to 500; SES accounted for 36% of variance in vocabulary in this sample. Arriaga et al. (1998) found that 80% of a sample of low-SES children between 18 and 30 months scored below the 50th percentile in productive vocabulary, using a test normed on a mid- to high-SES reference group. Comparing children of college-educated mothers to children of high school-educated mothers, Hoff-Ginsberg (1998) found SES-related differences in the size of the vocabularies they used in spontaneous speech. SES accounted for 5% of the variance in children's vocabulary in this sample.

Other studies using spontaneous speech, maternal report measures, and standardized tests show similar findings, with the magnitude of the SES-related differences depending on the range of SES in the sample studied (Dollaghan et al., 1999; Pan et al., 2005; Rescorla, 1989). For example, SES accounted for less than 1% of the variance in vocabulary assessed via maternal report using the MacArthur Communicative Development Inventory (MCDI) in a fairly homogeneous, middle-class sample (Fenson et al., 1994). Snow (1999) reported that SES differences are greater for measures of productive vocabulary than comprehension vocabulary, but Wells (1986) reported that the clearest SES-related difference is in oral comprehension. These vocabulary differences have long-term consequences. Vocabulary is a fundamental predictor of school success, and vocabulary deficits are one of the primary reasons that lower SES children enter school at greater risk for failure than their high-SES peers (Snow et al., 1998).

SES Differences in Grammar

SES-related differences in grammatical development have also been found. Children from higher social strata have been found to produce longer responses to adult speech (McCarthy, 1930), score higher on standardized tests that include measures of grammatical development (Dollaghan et al., 1999), produce more complex utterances in spontaneous speech as toddlers (Arriaga et al., 1998) and at age 5 years (Snow, 1999), and perform significantly better on measures of productive and receptive syntax at age 6 years (Huttenlocher et al., 2002). As an indicator of the magnitude of these effects on grammatical development, the low-income sample studied by Snow (1999) had an average mean utterance length (MLU) at age 3;9 that would be typical of children more than a year younger according to norms based on a middle-class sample. At age 5;6, they had an average MLU typical of middle-class children aged 3;1. Arriaga et al. (1998) found that 70% of low-income children were below the 50th percentile on the MCDI measure of sentence complexity. The SES-related differences are not in whether or not children can use complex structures in their speech, but in the frequency with which they do so (Huttenlocher et al., 2002; Tough, 1982).

Effects of SES on grammatical development are not as large or reliable as effects on vocabulary; some studies have found no relation between SES and measures of children's syntactic development (Hoff-Ginsberg, 1998; Hoff and Tian, 2005; Jackson and Roberts, 2001; Noble et al., 2005). A reason for these inconsistent findings is suggested by the finding in Vasilyeva et al. (2008) that SES was not related to measures of early mastery of basic syntactic rules but was related – in the same sample of children – to later differences in the use of more complex structures.

SES Differences in Communication

Studies of school-aged children find SES-related differences in the communicative purposes to which language is put, such that children with less educated parents less frequently use language to analyze and reflect, to reason and justify, or to predict and consider alternative possibilities than children with more educated parents. It has been suggested that the structural differences in children's language associated with SES may be a by-product of these functional differences (Tough, 1982). In an early sociological analysis of class and language, Bernstein (1970) similarly argued that higher and lower SES children do not differ in language knowledge but the differences in the communicative burden carried by language give rise to differences in the amount, the structure, and the lexical repertoire of the speech produced.

SES-related differences in school-aged children also appear in the ability to communicate meaning through language and to draw meaning from language – sometimes referred to as speaker and listener skills (Lloyd et al., 1998). In the referential communication task, which requires children to describe one item in an array of objects so that a visually separated listener with the same array can identify that item, lower SES children are less able than higher SES children to produce sufficiently informative messages and to use information in messages addressed to them to make correct choices (Lloyd et al., 1998). Children from lower socioeconomic strata also perform less well than higher SES children in solving mathematics word problems. That some of this difference is attributable to language ability, not mathematical ability, is suggested by evidence from one sample of lower SES children who showed poorer performance than higher SES children in word problems and in tests of verbal skills but who did not differ in their performance in math calculations (Jordan et al., 1992).

In sum, the findings are clear that children from different socioeconomic strata display different levels of language skill across multiple domains of language. It is also true that the specifics of SES-language relations and the size of the effects depend on the particular language outcome and the range of SES under consideration.

Other SES-Related Differences

In addition to these SES-related differences in vocabulary, grammar, and communication, there are SES-related differences in children's narrative skills, in their phonological awareness, and in their speed of language processing. The narratives produced by lower SES children are less sophisticated than the narratives produced by middle-class children of the same age, when assessed in terms of topic coherence and

independence from the nonlinguistic context (Heath, 1983; Vernon-Feagans et al., 2001). Lower SES children show lower levels of phonological awareness than middle-class children, with the size of the SES-related difference increasing from the age of 2 to 5 years (Bowey, 1995; Lonigan et al., 1998; McDowell et al., 2007). Lower SES children are also slower in accessing the words they know (Fernald et al., 2012).

In sum, a substantial body of evidence argues that the effect of SES on children's early language skills is pervasive and robust. The size of the effect differs depending on the range of SES being considered, the age of the children, and the aspect of language under consideration, but differences as large as 1 standard deviation are frequently observed and larger differences are also possible. Using age as a measure of the size of the SES-related difference, there are findings that children from low-income backgrounds are a year or more behind their middle-class counterparts (e.g., Snow, 1999).

It is important to note that neither low- nor high-SES children are monolithic in their language skill, that substantial individual differences exist within both populations, and that the distributions of skills among lower and higher SES children overlap (Hoff, 2003a,b; Pan et al., 2005). It is also important to note that low-SES children have unique linguistic strengths that are not captured by the procedures and tests most frequently used in research. Arguments for the unique skills of lower SES children tend to be in the form of ethnographic studies of specific populations and sometimes of particular uses of language that are unique to those populations. For example, Heath (1983) described the narrative skills displayed by very young boys in a rural, lower SES African-American community in the southeastern United States. Boys under the age of 4 years were able to hold the floor and engage the attention of adults with the stories they told, using a variety of poetic devices, sound effects, and accompanying movement. The narrative cohesion that is part of standard assessments of children's narrative skill is not a valued property of stories in this community. Similar skills in low-SES African-American boys have been described by Vernon-Feagans et al. (2001), who also described the children's narratives as being jointly constructed with other, older children – in contrast to the narrative performances of mainstream children, which are often monologues. Research with both European-American and African-American children has described other complex skill sets that lower SES children must master including those used in teasing interchanges (Miller, 1986), in ritualized insults (Abrahams, 1962), and in the combination of improvisational rhymes, steps, and hand claps that form the 'steps' performances of preadolescent African-American girls (Gilmore, 1986).

In addition to their description of the particular skills of particular groups, these studies make the broader point that there is substantial sociocultural variation in norms for language use that can make children from nonmainstream backgrounds look deficient when viewed from the perspective of mainstream expectations, while they are not at all deficient according to the norms for their own group. A similar argument applies to the interpretation of standardized test scores, which are frequently developed and normed using middle-class reference groups and may not tap the skills of children from other backgrounds. In the extreme, this line of reasoning argues that any comparison of language development across socio-economic strata is conceptually ill-founded because lower SES children are learning a different style of language use than higher SES children (see Hoff, 2013). The argument is that lower SES children have different language skills than higher SES children, but they do not have deficient language skills. It is possible, however, for there to be both stylistic differences and differences in language knowledge and skill, and the weight of the evidence argues that differences in knowledge and skill exist. Only two studies have reported SES-related differences in children's language in the direction of lower SES children being more advanced on measures of language knowledge. Both used the MCDI, and both attributed their findings to lower SES mothers' tendencies to overestimate their children's abilities (Feldman et al., 2000; Fenson et al., 1994).

Sources of SES-Related Differences in Language Development

The observed relations between SES and child language could be the result of several factors including (1) biologically based differences in children's abilities, caused by genes or health; (2) global effects of differences in family functioning and home environments (Linver et al., 2002); and/or (3) specific effects of differences in language-learning experiences (Hoff and Naigles, 2002; Hoff-Ginsberg, 1998). A substantial body of evidence argues for the third hypothesis that SES-related differences in children's language skills are the result of SES-related differences in their language experience.

Evidence of SES-related differences in mothers' child-directed speech abounds. Compared to mothers with more education, mothers with less education talk less to their children, and the nature of the speech they address to children is less supportive of language development than is the speech of more educated mothers. Lower SES mothers address speech to their children more frequently for the purpose of directing their children's behavior and less frequently for the purpose of eliciting and maintaining conversation (Hart and Risley, 1995; Hoff, 2006). In talking to their children, lower SES mothers make use of a smaller vocabulary, less complex syntactic structures, and less variety among the syntactic structures used, compared to higher SES mothers (Hoff, 2003a,b; Huttenlocher et al., 2007). Lower SES mothers have been found to spend less time in mutual activities with their children than do middle-SES mothers, and their conversations do not necessarily rely on their children's speech (e.g., Bee et al., 1969; Farran and Haskins, 1980).

Multiple studies have found that the properties characteristic of higher SES mothers are positive predictors of children's language development – even within SES (Hoff, 2006; Huttenlocher et al., 2010). Children who experience more responsive verbal environments, who hear more speech, who hear a richer vocabulary, and who hear a greater variety of syntactic structures acquire language more rapidly than children who hear less speech and who hear speech with lower levels of these supportive features (Hoff, 2006). One study found that properties of maternal speech fully mediated an SES-related difference in 2-year-olds' vocabulary (Hoff,

2003a,b). Evidence that the relation between input and language acquisition is causal, and not just a reflection of genetically based similarity in the verbal skills of mothers and children, comes from studies of teacher input effects. Children whose teachers provide more language-advancing input progress more in their language over the course of the school year than children with teachers whose language use is less supportive (Dickinson and Porche, 2011; Huttenlocher et al., 2002).

The sources of SES-related differences in language skills among older children are less directly studied. It is clear, however, that school does not eliminate the early-appearing differences. Rather, language skills at school entry predict later language and literacy skills (Dickinson et al., 2003; Muter et al., 2004; NICHD Early Child Care Research Network, 2005). SES-related differences in children's language skills at school entry are thought to play a large role in explaining the persistent SES-related achievement gap (Hoff, 2013).

Theoretical Implications of Relations Between SES and Language Development

Each of the candidate explanations of the SES–child language relation derives from a broader scope theory of how and to what extent the environment influences development in general, and language acquisition in particular. One view is that development, in particular language development, unfolds following a genetic blueprint (e.g., Pinker, 2002). The alternative view, of course, is that the environment plays a substantial role, and the evidence that SES-related differences in children's language development have their source in differences in their experience supports the latter view. Pointing to the environment, however, does not explain how the environment exerts its influence. It could be that the effect of the environment is global. That is, supportive environments benefit all aspects of development and unsupportive environments impede them. The fact that the effects of SES are pervasive and cross developmental domains is consistent with this global effect model.

A variety of evidence argues for the principle of environmental specificity, however. According to this principle, different aspects of the environment influence different aspects of development (Wachs, 1991). For example, the aspects of maternal behavior that predict language development are different from the aspects of maternal behavior that predict play development (Lyytinen et al., 2003; Tamis-LeMonda and Bornstein, 1994). Within language, the aspects of experience that influence the development of communicative skill are different from the aspects of experience that influence the development of language knowledge (Bernicot and Roux, 1998; Hoff-Ginsberg, 1998; Wachs and Chan, 1986). It is also likely that the input requirement for word learning and the input requirement for learning grammar differ, and that different types of words and different aspects of grammar further make their own requirements of experience. One reason that SES effects are more reliably observed in vocabulary than grammar and more for later than earlier grammatical acquisitions may have to do with the different requirements these acquisitions make and the relation of SES of each of those properties of input. For example, Huttenlocher et al. (2010) have argued that SES differences appear for later and not earlier grammatical development because early acquisitions depend on features of input that are always available while later acquisitions depend on features of input that vary as a function of education.

Conclusion

To sum, there is ample evidence in the literature that both the environments in which children acquire language and the rate of their language development vary as a function of family SES. It has been documented extensively that mothers from different socioeconomic strata interact with and talk to their children differently, and that these factors influence the rates at which children acquire language. The weight of the evidence suggests that SES affects children's opportunities for communicative interaction and the availability of language input with the consequence that, even after effects of language style are taken into account, the rate of children's language development differs as a function of SES. The evidence that SES-related differences in parents' speech cause SES-related differences in children's language development is consistent with theoretical approaches that give experience an important role in the language acquisition process.

Abstract

Language disturbances often occur after lesion – usually stroke – in the left hemisphere. In this article we aim to review methods of treatment and remediation of aphasic deficits. We first discuss the underlying neural mechanisms of recovery after stroke. We then focus on the several traditional approaches to aphasia rehabilitation and further refer to contemporary noninvasive, such as constrained-induced therapy, and invasive, such as pharmacological augmentation, treatments. Issues on efficacy of aphasia therapy are also discussed.

Introduction

Pierre-Marie claimed that there is a single form of language impairment, in the sense that only Wernicke's aphasia manifests symptoms that reveal a real cognitive deficit, and subsequently a breakdown of the neural language network. Patients with *aphemie*, described earlier by Broca, were considered to be individuals who, while suffering from anarthria, retained their core language-processing abilities. Global aphasia was the result of a lesion affecting both posterior temporal cortices, thus producing aphasia, and 'Marie's Quadrilateral,' a region including the insula, the underlying white matter, and subcortical nuclei, thus producing anarthria (Lecours et al., 1992; Tesak and Code, 2008). Marie's view seems nowadays to be oversimplified, since accumulating data from neuroimaging and lesion studies reveal a rather complex image with regard to language function and linguistic impairments. Nevertheless, his argument still stands: a linguistic disorder must have a cognitive component in order to be defined as such. Communications problems may arise from a variety of clinical conditions, such as dysarthria, stuttering, dysprosodia, etc. However, in the present article we will focus on acquired language disturbances due to underlying cognitive impairments resulting from focal or diffuse brain lesions. The generic term 'aphasia' is often used to describe such disturbances, which are usually due to a cerebrovascular accident (CVA). In the following sections we will discuss two major issues: recovery from stroke, and the variety of approaches and methods with regard to aphasia therapy.

Recovery after Stroke

Brain's capacity for reorganization after injury demonstrated in several studies (see, for example, the remarkable case of Alex, published by Vargha-Khadem in 1997, a 9-year-old boy who regained linguistic abilities after left hemispherectomy) clearly indicates that plasticity is the essence of recovery. On the basis of the relevant literature, it can be asserted that post-stroke recovery of cognitive functions is a gradual process that mainly takes place during a time-window of 1 year post-onset. The majority of stroke patients will show signs of significant recovery during the first 6 months (see, for example, Nicholas et al., 1993). The first 3 months after the CVA are considered to be the subacute post-stroke period (e.g., Gottesman and Hillis, 2010). Studies on cognitive impairment resulting from CVA suggest that the greater bulk of recovery can be observed within this particular timeframe (Demeurisse et al., 1980; Engelter et al., 2004; Hachioui et al., 2013; Lazar et al., 2010; Laska et al., 2001; Pedersen et al., 1995; Pickersgill and Lincoln, 1983; Sarno and Levita, 1971; Stone et al., 1992). According to general consensus, aphasic patients can be characterized as chronic after the 6-month post-onset period. However, there are findings reported in the literature that contradict the notion that recovery is restricted in the 3-month post-stroke period suggested above (e.g., Smania et al., 2010). Furthermore, it must be clarified that even if spontaneous recovery is limited in the acute and post-acute phase, improvement of linguistic abilities can be achieved also in chronic aphasia, provided that an appropriate treatment is implemented (Basso, 2003). It should be further noted that the rate and time spectrum of recovery is not uniform for all patients and heavily depends on individual differences. Several factors, such as lesion type, volume and locus, age, and initial severity, may affect the extent and rate of recovery. In general, advanced age, increased initial severity, cerebrovascular etiology, and extended lesions are related to poor prognosis (Kertesz and McCabe, 1977; Lazar et al., 2008; Maas et al., 2012; Pedersen et al., 1995, 2004; Reineck et al., 2005).

Observed recovery depends also on the specific function or aphasic syndrome studied. For example, in the case of patients with nonfluent aphasia due to left frontal lesions, clinical practice indicates that recovery of motor abilities usually precedes that of speech output. But even when making comparisons between more similar aspects of brain function, such as two components of verbal communication, one can find variability. One study recruited a mixed sample of 74 fluent and nonfluent aphasic patients, in order to investigate recovery of expressive and receptive abilities. During a period of 1 year, the patients were tested three times on several measures of spontaneous speech and sentence comprehension. There was no overall clinical improvement with regard to spontaneous speech. On the other hand, there was found considerable, significant improvement in sentence comprehension tests (Prins et al., 1978). It has been also demonstrated that different aspects of language,

such as phonology, semantics, and syntax components can be differentially affected (Hachioui et al., 2012), and follow distinct recovery patterns, with verbal communication being the latest to recover, during the first 6 months post -stroke (Hachioui et al., 2011, 2013; Smania et al., 2010). Another study by Laska et al. (2001) assessed the evolution aphasia subtypes from onset till 18 months post-stroke, as well as the recovery rate for each aphasic syndrome, by examining a group of aphasic patients in the acute stage, 3, 6, and 18 months after the occurrence of CVA. Recovery was observed for a great proportion of the whole aphasic sample (with one-fourth of the patients having completely recovered). Concerning evolution patterns for the different aphasia subtypes within the first 18 months post-stroke, most global aphasias evolved to mixed nonfluent, most Wernicke's aphasia to conduction, mixed, fluent, or transcortical sensory, and most patients initially diagnosed with conduction aphasia recovered completely. It should be, however, noted that the authors do not provide any information on whether patients received any kind of therapy or not, thus there is still a possibility of existing confounding factors with regard to outcome in the particular study. In other words, improvement cannot be certainly attributed to spontaneous or treatment-induced recovery, or even to a combination of both. Earlier research on the natural course of aphasia has also shown a gradual evolution reflected in taxonomic changes. Different patterns and rates of recovery among syndromes have also been observed (Sarno and Levita, 1979). Kertesz and McCabe (1977) studied 93 aphasic patients during the first year of recovery. While there were different patterns of recovery, i.e., patients with global aphasia showing in general rather poor prognosis in contrast with conduction, Broca's, and Wernicke's aphasics, the authors observed a general trend toward anomic aphasia, which was a common end-stage of evolution. Moreover, in accordance with Laska et al. (2001), their findings suggested that complete recovery occurred rather frequently among conduction aphasics, as well as patients with anomic and transcortical aphasia. A somewhat contradictive conclusion is drawn from the study of Nicholas et al. (1993), who performed consecutive aphasia assessments of 21 patients with 6-month intervals during a period of 2 years post-onset. Even though their findings indicated a significant improvement in communicative functions at least for up to 18 months post-stroke, the authors failed to find any changes with regard to aphasia classification in the aforementioned 2-year period. Further evidence suggesting stability of aphasia syndromes in the course of time is provided by Basso et al. (1982).

From a neurological perspective, a brain lesion causing various cognitive deficits should not be viewed as a stable and permanent condition, but as a snapshot of the ongoing recovery course. Longitudinal functional imaging studies show that brain reorganization is a highly dynamic process – similar to learning processes in healthy individuals – based on the emergence of new connections between the remaining modules of the shattered system (Rijntjes, 2006). In the early stages of the acute phase, there are two phenomena that play an important role in recovery: penumbra and diaschisis. Penumbra refers to underirrigation of a perilesional region, the penumbra zone, where neural cells are still partially functioning. It tends to diminish within the hyperacute phase, either spontaneously or aided by pharmaceutical treatment (Potagas et al., 2013; Ginsberg, 2003). Diaschisis is a notion originally introduced by von Monakow (1914), and refers to the supposed loss or decrease of function in the early period in structurally unaffected brain regions connected to the damaged area, in ipsilateral and contralateral areas (see also Feeney and Baron, 1986; Finger et al., 2004). Regression of these two phenomena is related to clinical recovery in the early period after stroke. A recent study by Saur et al. (2006) showed that language recovery in aphasia occurs in three stages: (1) reduced activation of the remaining left perisylvian regions in the acute phase, (2) increased activation of homologue right hemisphere regions, and (3) normalization of activation. However, it is suggested that reorganization processes are differentiated on the basis of lesion localization (Rijntjes, 2006) and type of impairment, with speech recovery depending on gradual left hemisphere activation changes and auditory comprehension recovery depending on both left and right temporal lobe activation (Price and Crinion, 2005). Few studies thus far have combined functional Magnetic Resonance Imaging (fMRI) and Diffusion Tensor Imaging (DTI) data to investigate the reorganization of brain mechanisms supporting language functions in the context of aphasia recovery. While such studies are limited to case reports (e.g., Heller et al., 2005), the necessity of longitudinal group studies is stressed by many authors. Crinion and Leff (2007) argue that such studies with larger patient samples and more detailed behavioral and lesion characterization are essential for the clinical diagnosis and treatment of aphasia, in the sense that they could elucidate the relationship between neuronal reorganization and recovery in chronic aphasic individuals.

Approaches to Aphasia Therapy

The interest on aphasia therapy grew rather slowly and reached a climax several decades after the seminal publications by Broca (1861, 1865), Wernicke (1874), and Lichtheim (1885), in which language disturbances were originally described in detail and defined as aphasic syndromes. Little attention was paid on rehabilitation during the first reign of the associationist theory, in the second half of the nineteenth century. However, after World War I several clinicians started working on possible treatment methodologies, which were mainly based on the idea that patients with aphasia had to relearn language abilities that have been lost, usually through repetition and drilling tasks. Aphasia rehabilitation started receiving more attention after World War II, due to the great numbers of rather young soldiers who suffered language disturbances after gunshot wounds. During this period the need for therapy with regard to older stroke patients with aphasia became more evident. The issue of aphasia was gaining popularity; the media started providing the public with relevant information, the request for rehabilitation increased, and several intervention techniques were devised (for a historical overview on the matter, see Basso, 2003). Up until now, several approaches have emerged, which will be briefly described below. The different approaches developed in the twentieth century obviously reflect distinct perspectives on aphasia. When a theory for the biological substrate of language and the underlying pathophysiological

mechanisms of aphasia is already formulated, it is inevitable for the methods of assessment and treatment to be defined on the basis of the theoretical hypotheses.

It has been suggested that the foundations of the so-called *classic* approach (otherwise called 'stimulation' or 'stimulation-facilitation' approach) have been established by the ideas of the holistic school, according to which language is a complex indivisible cognitive function that cannot be divided in terms of cortical representation to discrete subserving brain modules (Basso, 2003). The main representative of the particular view is Hildred Schuell. According to her view, aphasia may be seen as a clinical condition determined by two factors. The first one is the severity of the aphasic disorder and the second is the accompanying deficits in other cognitive domains, such as perceptual and sensorimotor. It is thus the degree of aphasia severity that differs among patients, and the distinct syndromes that may be observed can be considered as an artifact due to the aforementioned comorbid deficits. In sum, there are not truly different aphasia subtypes, but different degrees of severity and various types of co-existing impairments (Schuell et al., 1962). The second assertion of the stimulation approach is that it's not the linguistic function per se that is lost in aphasia, rather than access to it. This notion is based on the voluntary/automatic dichotomy, which in turn is supported by the common observation that linguistic behavior of aphasic patients is far from constant, in the sense that even severely impaired patients can produce speech under certain situations. There are many anecdotal reports of severely nonfluent patients producing utterances in a rather effortless way, when in any kind of stress. The patient reported by Jackson (1878/1958), suddenly shouting 'fire!' is such a case. Other examples are patients swearing when irritated. The famous Monsieur Tan is said to fluently utter the curse '*Sacré nom de Dieu*.' There was also a patient in our clinic with a severe nonfluent aphasia due to which he could only communicate through single words. He had right hemiplegia, therefore writing was quite difficult for him (note he was right-handed). When asked to copy a sentence with his left hand, he eloquently replied cursing at one of the authors (DK), using a four-word utterance. In the context of stimulation therapy, since aphasia cannot be further divided in distinct syndromes, therapy could be unitary for all patients, aiming to enhance access to language components. Given that aural comprehension is a key feature of language processing, rehabilitation is facilitated via auditory stimulation (Duffy and Coelho, 2001). Repetition of the stimulus is essential, while the complexity and length of the verbal material used in intervention sessions must be adjusted to the patient's abilities (Schuell et al., 1964).

The *behavioral* approach is based on operant conditioning, a notion introduced by the pioneer behaviorist B.F. Skinner. According to the Behaviorism's view only external stimuli and observed behavior can be studied directly, while brain function cannot, thus being beyond the scope of psychological research. Skinner (1957) claimed that verbal behavior is not different from any other aspect of human behavior; therefore it is subject to the same rules and can be modified in a similar way. By applying the principles of operant conditioning in aphasia therapy, the therapist can formulate a so-called *programmed instruction*, i.e., a carefully designed intervention program in which both the therapist's and the patient's behaviors are predetermined, in order for the latter's verbal behavior to be essentially modified, via manipulation of the external stimuli. In order to achieve this modification, the therapist makes use of two techniques: fading and shaping. Fading refers to facilitation of a response that is presumed to exist in the patient's repertoire, via facilitation based on selected antecedent stimuli. When the patient becomes able to provide the particular response without any help, the facilitation is gradually faded away. Shaping refers to facilitation of an unavailable response by manipulation of similar existing responses (for more details, see Basso, 2003).

The *functional reorganization* approach was introduced by Luria in the mid-twentieth century (Luria, 1963, 1970; Luria et al., 1969). Luria believed that linguistic functions are supported by a neural network consisting of several brain regions, each of them related to different components of verbal processing. Consequently, the type of aphasia resulting from brain damage would be dependent on the lesion locus. In terms of rehabilitation, the specifics of the impaired linguistic component must be firstly identified. Then, an intervention program focusing at the lost ability is designed, where aid is provided by the therapist in order for the patient to achieve maximum performance on a related language task. The program consists of specific tests which must be strictly followed. The final goal is functional reorganization; other, previously non-language related neural networks to be involved in linguistic processing, usually through a shift from a lower/automatic to a higher/voluntary level. Similar theoretical underpinnings are related to the *processing* approach. This view is based on cognitive models created to explain normal linguistic functions. Such models argue that each language component reflects a complex cognitive function supported by a network of distinct modules, not necessarily linked to an exact site in the brain, that process different kinds of verbal information (Hillis, 2001). The first step for rehabilitation is to identify the deficit and the underlying impaired module. Intervention then progresses by focusing on remediation of the affected cognitive processes and/or compensation through the spared modules (Hillis, 2001, 2002).

The *pragmatic* approach (also called 'functional communication' approach) is concerned with the patient's general communicative ability. Instead of assessing the accuracy of verbal output, therapists that adopt this view are rather interested in the efficacy of the message per se. Language is defined as a means of verbal communication, always examined within the particular real-life context. Therefore, aphasia is a communication disorder, rather than just a language breakdown. On the basis of this alternative perspective, the final goal of therapy is to enhance the ability of the patient to convey meaning to others, by any means available. Several studies have pointed out that aphasic patients' general communication capacity often seems to be better preserved compared to specific linguistic functions (Foldi et al., 1983; Kadzielawa et al., 1981; Wilcox et al., 1978). This is also evident in everyday clinical practice. Based on our experience, when not formally tested, aphasic patients can communicate more effectively, expressing feelings and ideas by using verbal along with nonverbal means, such as gestures. A remarkable

communicative capacity can be seen, for example, during self-help group sessions, where severely nonfluent patients engage in conversations, demonstrating a contrasting image with regard to their assessment-based clinical profile. It should be, however, noted that impairment-focused therapy can improve communication capacity in real-life circumstances (Carragher et al., 2012). The best-known and most widely used pragmatic approach is PACE (Promoting Aphasic's Communicative Effectiveness), developed by Davis and Wilcox (1985). In PACE-based intervention programs, the therapist aims to enhance the patient's communicative strategies, verbal or not. Every session must include conveyance of new information between the patient and the therapist, both of whom participate equally in this exchange, by sending and receiving messages. Patients are encouraged to use any means necessary, including words, drawing, writing, and gestures, in order to communicate. A step further within the context of the pragmatic approach would be to extend treatment, by including real-life communication in natural environment and involving partners in therapy (e.g., Kagan, 1998; Lubinski, 2001; Nykänen et al., 2013; Wilkinson et al., 2010). It should be, however, noted that the particular approach, although interesting, has been criticized on grounds of poor ecological value, scarce evidence in the literature, and limited clinical utility for the whole spectrum of aphasic disorders (Basso, 2003).

According to the *neurolinguistic* approach, language is governed by an internal system of organization rules. Post-stroke aphasic deficits are thus analyzed in the framework of a linguistic theory. The first comprehensive linguistic interpretation of aphasia was introduced by Jakobson (1964), who suggested two integral components of language processing: selection, which refers to the operation of selecting the appropriate word among alternatives on a similarity axis, and combination, which refers to the operation of combining the selected words along the contiguity axis. The model further enriched by other dichotomies and deficits in different axons correspond to specific aphasic phenomena (such as paraphasias or agrammatism) or even taxonomic categories. Several authors consider the linguistic theory to be essential for aphasia therapy (e.g., Hatfield, 1972; MacMahon, 1972). Given that a particular linguistic impairment is at the core of the treatment design, it has been claimed that a detailed analysis of distinct features of the aphasic syndrome allows the formulation of a highly specialized intervention program, strictly targeted at the specific deficit (Weniger et al., 1980). Therapists in favor of this approach often build their intervention strategies on the basis of linguistic principles, such as Chomsky's (2002) ideas of competence/performance dichotomy (e.g., Weigl, 1961; Weigl and Bierwisch, 1970) or transformational grammar (e.g., Naeser, 1975). Overall, the neurolinguistic approach has been extensively implemented through intervention strategies aiming at rehabilitating various syntactic (Helm-Estabrooks and Nicholas, 2000; Loverso et al., 1988; Naeser, 1975; Thompson, 2001; Weniger et al., 1980; Wilk and Paradis, 1993), phonemic (Naeser et al., 1986; Weniger et al., 1980; Wilk and Paradis, 1993), and lexical (Weniger et al., 1980; Wilk and Paradis, 1993) deficits. Nevertheless, the contribution of neurolinguistics in aphasia remediation remains under question, since the particular approach suffers many limitations (e.g., rather vague suggestions for founding therapy on linguistic principles; see also Basso, 2003).

There are several heterogeneous therapies that were developed in Boston, and were based on the neoassociationist theory. Basso (2003) groups them under the generic label *neoassociationist* or *neoclassic* approach, while acknowledging this heterogeneity among them. The theoretical background of these therapies is that language is subserved by a complex neural net that is composed of cortical faculties, each specialized for a particular linguistic function, interconnected by association with white matter fibers. Different types of aphasia are due to lesions affecting different parts of the perisylvian language network. Therefore, remediation techniques vary depending on the syndrome, and there are many therapy programs specially designed for specific taxonomic categories or discrete aphasic symptoms (Helm-Estabrooks and Albert, 1991). In general, the therapist focuses on the level of the observed disorder (i.e., whether it is phonemic, lexical, syntactic, semantic, etc.), and intervention is heavily based on stimulation. Among the various types of treatment within the spectrum of neoclassic theory, one can find several different views on language function and aphasia rehabilitiation. For example, according to the Language-Oriented Treatment (Bandur and Shewan, 2001; Shewan and Bandur, 1986), language can be separated in distinct modalities, which in turn are further divided in mutually exclusive areas. The areas are set in order of increasing difficulty and then the therapist attempts to remediate a specific modality, by using cues hierarchically organized in terms of effectiveness (see, for example, Best et al., 2013). Melodic Intonation Therapy (Albert et al., 1973; Norton et al., 2009; Sparks, 2001; Sparks et al., 1974; Sparks and Holland, 1976) utilizes the right hemisphere's music processing abilities, by using intonation and rhythm in the context of a hierarchically structured program, in order to facilitate sentence production. The neoassociationist umbrella also includes many other treatment methodologies, designed specifically to rehabilitate particular symptoms or aspects of a defined syndrome, such as Treatment for Wernicke's Aphasia (Helm-Estabrooks and Albert, 1991), Treatment of Aphasic Perseveration (Helm-Estabrooks et al., 1987), Helm Elicited Language Program for Syntax Stimulation (Helm-Estabrooks, 1981; Helm-Estabrooks et al., 1981), and Voluntary Control of Involuntary Utterances (Helm-Estabrooks and Albert, 2004; Helm and Barresi, 1980).

There are always new methods suggested for aphasia rehabilitation, more or less invasive. A rather new one is Constrained-Induced Therapy, originally developed by Taub (Taub, 1980; Taub et al., 1998, 1993, 1999) for remediating motor deficits, and used in aphasia rehabilitation for about a decade (Cherney et al., 2008; Meinzer et al., 2012). This view stresses the importance of forcing the patient to use his/her impaired ability to convey a message, excluding other routes of communication (see, for example, studies by Kirmess and Maher, 2010; Pulvermüller et al., 2001; Szaflarski et al., 2008). More invasive therapies have also been implemented in aphasia. Pharmacotherapy, for example, has provided rather promising (even though preliminary) evidence that, when combined with noninvasive

remediation methods, can be beneficial with regard to post-stroke aphasia's outcome (Berthier et al., 2011; Cherney, 2010). Several dopaminergic, cholinergic, noradrenergic, and glutamatergic agents have been used in this field (Berthier et al., 2009, 2011; Gill and Leff, 2014; Moscowitch et al., 1991; Seniów et al., 2009; Small and Llano, 2009; Tanaka et al., 1997; Walker-Batson et al., 2001; Whiting et al., 2007). Overall, research on pharmaceutical treatment of aphasia has provided useful findings indicating improvement in a wide range of linguistic abilities, such as naming, articulation, comprehension, and phonological skills (Berthier et al., 2011). Another biological approach to language remediation is related to the use of Transcranial Magnetic Stimulation (TMS) in aphasia. Based on the presumption that post-stroke overactivity of the right hemisphere homologues may be maladaptive for recovery, TMS has been applied to right cortical areas, in order to suppress their excitability (Martin et al., 2004; Hamilton et al., 2011). Recent studies' preliminary results suggest that there may be a possible beneficial role of TMS application combined with traditional language therapy with regard to aphasia outcome (Barwood and Murdoch, 2013; Naeser et al., 2005a,b; Szaflarski et al., 2011). Alternative methods of cortical stimulation have also been used in this context (e.g., Cherney et al., 2012).

Efficacy of Aphasia Therapy

There are many remediation techniques implemented in aphasia therapy, that may refer to the basic approaches described above, or extend beyond them, including group therapy (Basso, 2003), psychosocial-driven intervention strategies (Code et al., 2003), or even therapy programs that utilize computers (Palmer et al., 2012, 2013), humor (Simmons-Mackie and Schultz, 2003), or dogs (LaFrance et al., 2007). However, the crucial question is whether aphasia therapy is beneficial or not. There is no clear-cut answer in the relevant literature. There are controversial views that argue in favor either of high efficacy or limited (or even naught) effectiveness of aphasia therapy (e.g., Kertesz and McCabe, 1977; but see also Basso, 2003 for a discussion). In any case, there is robust evidence that different kinds of therapy are beneficial at least for some patients. As mentioned above, new intervention methodologies, such as TMS and pharmacological augmentation have provided promising results, by showing post-therapy improvement of several linguistic skills, such as naming and comprehension (e.g., Barwood and Murdoch, 2013; Berthier et al., 2011; Gill and Leff, 2014; Martin et al., 2004; Naeser et al., 2005a,b; Walker-Batson et al., 2001; Whiting et al., 2007). But older, more conventional therapies have been proven to be rather efficient (Aftonomos et al., 1999; Basso et al., 2011; Nickels, 2002; Shewan and Kertesz, 1984; Szaflarski et al., 2008), even for chronic (Basso and Caporali, 2004; Basso and Macis, 2011; Marangolo et al., 2013; Moss and Nicholas, 2006; Pulvermüller and Berthier, 2008) and severe aphasia (Basso, 2010). Furthermore, there is evidence that therapy may induce neuroplasticity in acute and also in chronic stages (Marcotte et al., 2012, 2013; Meinzer et al., 2004; Schlaug et al., 2009). An overall view on aphasia therapy efficacy has been recently offered by Basso (2003). The author performs a thorough review of the available literature, including meta-analyses, group, and single-case studies and concludes that remediation of language disorders appear to be generally efficient. A final remark should be made on the time frame of an intervention program in relation to effectiveness and final outcome. With regard to the starting point of therapy, it has been suggested that remediation strategies should be implemented at the acute phase (Godecke et al., 2012; Worall et al., 2013). Furthermore, several authors stress the importance of increased intensity, which is considered to be extremely beneficial for rehabilitation (Basso, 2005; Basso and Caporali, 2001; Bhogal et al., 2003; Code and Petheram, 2011; Godecke et al., 2012; Meinzer et al., 2004; Pulvermüller and Berthier, 2008; Sage et al., 2011; but see also Cherney et al., 2011; Marshall, 2008).

Abstract

The relationship between the archeological and linguistic records of human activity is very broad, extending from modern human language origins amongst our Paleolithic forebears onward into the usage of 'texts' (both written and oral) to assist interpretation of the archeological record of recent human history. This article, however, will be more specific, and is concerned essentially with late prehistory, prior to the development of written records, and with the question of how the world's major language families have originated and spread. It is also concerned with how linguistic information on this topic can be integrated with the archeological record of human expansion and migration during the past 10 000 years. This time span is chosen because extant language families shed little light on human affairs during the Pleistocene (2.6 million to 12 000 years ago), given that languages change constantly in ways that have slowly but inevitably erased traces of once-existing Pleistocene linguistic landscapes.

This article is concerned with the warm and relatively wet post-glacial period of time known as the Holocene (10 000 BC to now), the period within which agriculture and unstoppable growth in the size of the human population have underpinned the world that we inhabit today, replete with its different languages, cultures, and biological populations. All extant language families, of hunters and farmers alike, trace their dispersal histories back to some point within this time span, to specific episodes of human migration and dispersal. Human societies and migrations, of course, existed and occurred during the Pleistocene, as did languages remotely ancestral to all existing language families. The Pleistocene can be investigated archeologically, but we cannot trace its languages in any direct way, except through comparative reconstructions of macrofamilies (e.g., Nostratic, Amerind, Dene-Caucasian – see Gell-Mann and Ruhlen, 2011). The results from using a macrofamily approach do not intersect easily with the archeological record, and this topic is not considered further here.

Language families of wide distribution across the world are shown in **Figures 1** and **2**. All existed, including Indo-European, to virtually their pre-AD 1500 limits before the recording of any actual history, whether it be from the Rigveda, Herodotus, Julius Caesar, or the British Empire. It is not possible to link the pre-AD 1500 distribution of any major language family to any episode of state formation in human history. All were created by the small-scale societies of prehistory, amongst societies of stone-using and sometimes metal-using farmers, pastoralists, and hunter-gatherers. Major language spreads in recent colonial history – English, Spanish, Russian, Chinese, and so forth – should not be confused with the origins of whole language families. Like these recent spreads, the major element behind the spread of whole language families in prehistory was always a movement of actual speakers of the ancestral languages, not purely language shift through secondary learning across linguistically unrelated communities. However, such migrant native speakers always mixed genetically with indigenous populations, when they existed. Some, such as the early Austronesians of the Pacific, were able to enter empty territories and thus colonize pristine landscapes.

Why do language families exist? Why are English and Bengali quite closely related, at least to a linguist, even if such relationship today would be totally puzzling to monolingual native speakers of those two languages? Johann Reinholt Forster and William Jones both knew the answer in the late eighteenth century (the former in 1774 while on Cook's second Pacific voyage for Austronesian, the latter in 1786 for Indo-European). As Jones put it so famously: "… no philologer could examine them all three [Sanskrit, Greek and Latin], without believing them to have sprung from some common source, which, perhaps, no longer exists" (Jones, 1993: 175). Reconstructing the common source is therefore essential if we are to broach the "why do language families exist" question.

Today, language history and the archeological record can be studied in combination to recover history at two major (but clearly overlapping) levels:

1. at the level of the individual language, ethnolinguistic group, or historical community; and,
2. at the level of the language family, or major internal subgroup within a family.

With regard to (1), it is very difficult to trace the identity into deep levels of prehistory of a specific ethnolinguistic or historical population (e.g., Celts, Greeks, Etruscans, Kurds, Jews), unless one is dealing with a very isolated region or an island where one can assume there has been no substantial population replacement or mixing during the period in question. Good examples of the latter would be certain Pacific islands, for example Easter Island or New Zealand, both fairly isolated since their first human settlements less than 1000 years ago by Polynesians (Kirch and Green, 2001). However, this article is not primarily concerned with such society- or culture-specific correlations.

Instead, it focuses on the study of languages as members of genetically constituted and evolving families. The member languages within a language family have inherited a common set of retentions from a so-called 'protolanguage' that can be reconstructed in part through the methodology of comparative linguistics. Such protolanguages, and their reconstructed sets of

Figure 1 The major language families of the Old World, overlaying the most significant regions of early agricultural development. The Fertile Crescent is suggested as the homeland region for Indo-European and Afroasiatic; Sub-Saharan Africa for Nilo-Saharan pastoralism and Bantu; East Asia for Sino-Tibetan, "Altaic" (including Turkic), Sino-Tibetan, Tai, Austroasiatic, Hmong-Mien and Austronesian; New Guinea Highlands for Trans New Guinea. The Pama-Nyungan languages of Australia are also shown. Original map by Clive Hilliker, ANU.

lexical meanings for items of material culture, can sometimes be associated with well-defined and well-dated archeological traditions as they spread, evolved and interacted through time and space. It is necessary to avoid circular reasoning here, but because the archeological and linguistic records of prehistoric human affairs are generated from completely independent data sets (languages on the one hand, the archeological record on the other), it is possible to compare reconstructions from both disciplines carefully in order to generate testable and convincing 'best explanations' (Fogelin, 2007).

Historical reconstruction at this level tends to be organized such that language families (e.g., Indo-European, Austronesian) are foregrounded as the major foci of enquiry, rather than archeological complexes. This is because language families are usually more sharply defined and reveal clearer patterns of phylogenetic inheritance than do archeological complexes (*see* Cultural Evolution: Phylogeny versus Reticulation). In such situations, archeology tends to be used to support or refute historical linguistic questions. For instance, where was the Indo-European homeland located, what lifestyle did its inhabitants enjoy, and when? We examine this question in more detail later. In addition, however, some archeological complexes of particularly wide distribution, internal homogeneity, and short time span, such as the Linearbandkeramik (LBK) early Neolithic of Central Europe (*c*.5400–5000 BC) and the Lapita cultural complex of the western Pacific (*c*.1300–800 BC), are also sometimes foregrounded as requiring a paleolinguistic identity. For instance, did the LBK correlate with early Indo-European linguistic dispersal through central Europe? Did Lapita correlate with Austronesian (Oceanic subgroup) linguistic dispersal through Melanesia into Polynesia?

To understand how the data of historical linguistics and archeology might be compared against each other to improve understanding of the human past, it is first necessary to state clearly the abilities and limitations of the two disciplines.

Language as a Source of Information on Human Prehistory

The branch of linguistics which is of most interest to prehistorians is that known as comparative historical linguistics, in which the structures and vocabularies of present-day or historically recorded languages are compared to identify families, and subgroups within these families. The methodology of comparative linguistic reconstruction is precise. Like the methodology of cladistics, as applied in biology, its main goal at the within-family level is to identify shared innovations which can identify language subgroups. Such subgroups comprise languages which have shared a common ancestry, separate from other languages with which they are more distantly related. Languages which comprise a subgroup share descent from a common 'protolanguage,' this having been in many cases a chain of related dialects. The protolanguages of subgroups within a family can sometimes be organized into

Figure 2 The major language families of the New World, overlaying the most significant regions of early agricultural development (Piperno, D., 2011. Plant cultivation and domestication in the New World tropics. Current Anthropology 52 (Suppl. 4), S453–S470). The Eastern Woodlands are suggested as the homeland for the Siouan and Iroquoian language families; Mesoamerica for Uto-Aztecan, Otomanguean, Mixe-Zoque, and Mayan; the Andes for Quechua and Aymara; southwest Amazonia for Tupi and Panoan; the Orinoco Basin for Carib; and northern South America possibly for Chibchan (and Arawak?). Original map by Clive Hilliker, ANU.

a family tree of successive linguistic differentiations (not always sharp splits, unlike real tree branches), and for some families it is possible to postulate a relative chronological order of subgroup formation. For instance, many linguists believe that the separation between the Anatolian languages (including Hittite) and the rest of Indo-European represents the first identifiable differentiation in the history of that family. Likewise the separation between the Formosan (Taiwan) languages and the rest of Austronesian (Malayo-Polynesian) represents the first identifiable differentiation within Austronesian.

The vocabularies of reconstructed protolanguages (e.g., Proto-Indo-European, Proto-Austronesian) can sometimes provide remarkable details on the locations and lifestyles of ancient ancestral communities, with many hundreds of ancestral terms and their associated meanings reconstructable in some instances. There have also been many attempts to date language subgroup history by a variety of methods based on lexical comparison, including glottochronology, Bayesian phylolinguistics, and the analysis of Levenshtein lexical distances (see discussions in Renfrew et al., 2000; Greenhill and Gray, 2012; Holman et al., 2011). Such methods always require calibration against real time using historical records, and can be affected by sociolinguistic situation and the intensity of ancient borrowing. Debates continue about their validity (Donohue et al., 2012), but there can be no doubt that the chronological answers they give often accord well with archeological dating, particularly for language families whose roots are suspected to correlate with the regional beginnings of agriculture (Bellwood, 2005).

The other major source of linguistic variation, apart from modification through descent, is that termed by linguists 'borrowing' or 'contact-induced change.' This operates between different languages, and often between languages in completely unrelated families. Borrowing, if identified at the protolanguage level, can be as much an indicator of the homeland of a language family or subgroup as can genetic structure. It can also reflect important contact events in language history.

Archeology as a Source of Information on Human Prehistory

Archeology is concerned mainly with the recovery and interpretation of the material remains of the human past, and the environmental contexts in which those remains were originally deposited. Such remains may be dated, and grouped into regional complexes of related components. Such complexes can then be compared with other complexes, and the boundaries between such complexes can be studied carefully. Some are sharply bounded, hence possible candidates for correlation with an ethnolinguistic group, while others are simply nodes of relative homogeneity in a kaleidoscope of ever-shifting patterning. Archeology alone cannot pinpoint ethnicity, unless of course it operates in an environment associated with literacy and the availability of written records. Even then, ambiguity can plague interpretation, as in the modern debate in British archeological literature about the definition and archeological history of the Celts (Collis, 2003). Any correlations between the archeological and linguistic records will always require care.

How Can Language Family History and Archeological Prehistory Be Correlated?

Correlation of the archeological and linguistic records is not always a simple matter. However, correlations can be made when language family distributions correspond with the distributions of delineated archeological complexes, particularly when the material culture and environmental vocabulary reconstructed for a given family at the protolanguage level correspond with material culture and its environmental correlates as derived from the archeological record. Many reconstructed protolanguages, for instance, have vocabularies which imply the existence of crucial categories within human economic and technological behavior, such as agriculture, domestic animals, pottery, and metallurgy, these all being identifiable in the archeological record.

The concept of the language family is sturdier than that of the archeological culture. This is important, because linguists have come to a remarkable level of agreement on the classification of the world's language families. Apart from a small number of creoles, mostly a result of recent historical European colonization and population translocation, the vast majority of the world's language families are clearly bounded in a classificatory sense and not beset with huge numbers of 'mixed' languages. As an example, the Indian subcontinent has been a region of interaction between the speakers of Indo-European and Dravidian languages for at least five millennia. Languages within these two families have borrowed extensively from each other, to the extent that the subcontinent is often referred to by linguists as a 'linguistic area' (a zone of widespread areal diffusion). Nevertheless, the subcontinent is not covered by languages which are half Indo-European, half Dravidian, chaotically mixed. This means that language families are coherent entities, capable of maintaining coherence and independence through long periods of time. As such, they are believed to carry traceable records of human history and to be associated, in their origins, with homeland regions and processes of population dispersal. Although some populations have changed their languages in the past, it is unlikely that language shift, as opposed to an actual dispersal of ancestral speakers of a protolanguage, could have been the main mode of dispersal of any major language family (Ostler, 2005). All of this means that the origins and dispersals of the protolanguages from which language families are created should correlate with major population movements, frequently on a scale which should be visible in the archeological record (Bellwood, 2008, 2009, 2010, 2013).

Some Examples of Language Family Origin and Dispersal Histories with Claimed Archeological Correlations

In the remainder of this article we examine some of the major language families of the world, and discuss recent literature pertaining to their origin locations and histories of dispersal. This literature is of course vast, and readers will find that much is reviewed in *The Encyclopedia of Global Human Migration* (Ness and Bellwood, 2013), and in Bellwood (2013). Many archeologists and linguists today recognize that some very

large language families could owe their initial creations to population dispersal as a result of population growth following on from the development of agriculture. If this is so, then the homelands of these particular families, to be discussed individually below, can be expected to overlap with the most important regions of early agriculture, as indeed seems to be the case for the Middle East, East Asia, and Mesoamerica (**Figure 1**). However, it is important to remember that many language families are associated totally with hunting and gathering populations, and presumably always have been, so their histories obviously will not involve this factor. Such hunter-gatherer families with recent histories of expansion include the Pama-Nyungan languages of Australia, Athabaskan in Canada and the US Southwest, and Eskimo-Aleut. In these cases, explanations for their expansion must also be based on factors of demographic growth and technological advantage, albeit not involving food production. Other families, such as Uralic, Algonquian, and Uto-Aztecan, have both agricultural and hunter-gatherer populations. In some of these cases it is possible that former agricultural peoples actually became hunters and gatherers in agronomically difficult environments. Examples include the southern Maoris of New Zealand and the Great Basin Uto-Aztecans (Hill, 2002; Bellwood, 2005).

As noted above, it is apparent that some languages and subgroups (but not whole language families) have been recorded as spreading over large distances in historical times, under conditions of statehood, religious evangelism, and colonialism. Thai in Thailand, the Chinese languages in southern China, Arabic in North Africa and the Middle East, and of course English and Spanish in their recent overseas colonies all come to mind here. In the twenty-first century, it is also apparent that lingua francas and national languages can spread rapidly as a result of educational policy, literacy, mass media, and sociolinguistic status. But it is more difficult to imagine such processes of language adoption as being of great significance amongst the small-scale societies of preurban prehistory. Nevertheless, many prehistorians have suggested that language replacement processes of this type, whereby people adopt a language deemed to be of high social status and abandon their original language, have been instrumental in the spread of some families. One such family is Indo-European, for which some linguists and archeologists have long agreed on a homeland in the steppes north of the Black Sea, followed by a spread into Europe by Late Neolithic and Bronze Age pastoral peoples with domesticated horses and wheeled transport (Anthony, 2007). According to this view, these people undertook their migrations into Europe between 4500 and 2500 BC, dominating and absorbing the older Neolithic societies in the process.

This view of Bronze Age conquest and language replacement for Indo-European dispersal has been challenged by the archeologist Colin Renfrew (1987, 1996), who opts instead for an association of early Indo-European languages with early Neolithic farming dispersal into Europe from Anatolia (Turkey). This view has been strengthened in recent years by new evidence for some quite dramatic population dispersal, associated with farming, commencing around 6500 BC from Anatolia into northern Greece and the Balkans (Özdoğan, 2013; and *see* Phylogeny and Reticulation in Prehistory for further discussion of relevant archeology and genetics). Farmers typically have larger populations than hunter-gatherers, and if farmers are not enclosed by other farming populations, or if they live in a region surrounded essentially by low-density hunter-gatherers, then expansion is a likely outcome, exactly as in the recent European colonial frontiers in Australia and western North America. So, while the agricultural dispersal hypothesis is no more 'provable' than many other hypotheses to explain language family origins, it does at least have the strong supporting factor of a historically demonstrable mechanism which can allow and encourage population expansion to occur. Such expansion need not mean extinction of all hunter-gatherers. In many ethnographic situations, hunter-gatherers have survived in the interstices of agricultural or pastoralist landscapes, perhaps for millennia.

Put simply, the farming dispersal hypothesis, as expressed in more detail elsewhere (Bellwood and Renfrew, 2002; Diamond and Bellwood, 2003; Bellwood, 2005, 2013), would see the protolanguages for Indo-European and Afroasiatic located in the wheat, barley, cattle, sheep, and goat early farming zone in the Middle East, with dispersals occurring, far to the east and west, mainly between 6500 and 3000 BC. Cyprus was actually colonized by boat from the Asian mainland as early as 9000 BC. By 4000 BC, Indo-European speakers had reached the British Isles. They penetrated much earlier toward Pakistan and Turkmenistan, commencing around 7000 BC, but only entered the upper Ganges basin around 3000 BC. Other ancient and extinct languages such as Sumerian and Elamite must also have existed, perhaps quite widely, in the Middle East well before 3000 BC, but these later became replaced by members of the more successful language families, especially the Semitic (Afroasiatic) and Iranian (Indo-European) languages. Some linguists have also suggested that Elamite was related to the existing Dravidian family of languages in southern India and Sri Lanka, which perhaps spread from northwestern regions of the subcontinent after the appearance there, around 3000 BC, of millet agriculture and cattle pastoralism.

Early Afroasiatic speaking populations carried agriculture, sheep, and goats from the Levant into northwestern Africa about 6500 BC, where they met existing populations of Nilo-Saharan speakers who had spread as hunter-gatherers through what is now the southern and eastern Sahara Desert during a wet climatic phase starting *c.* 9000 BC. These Nilo-Saharan speakers in turn adopted pastoralism, and some later moved southward into Kenya and East Africa. Further west, Niger-Congo expansion began also during the early Holocene wet phase in the southwestern Sahara, but Bantu subgroup speakers spread most dramatically over much of central and southern Africa after 1000 BC, in association with millet agriculture, cattle pastoralism, and the use of iron. This expansion led to considerable retraction of the original distribution of the large and much diversified group of languages termed Khoisan, such that they only survived amongst hunters and pastoralists in the southern parts of the continent when Europeans arrived. Bantu languages today dominate almost all of Sub-Saharan Africa, except for the far south.

Likewise, Afroasiatic and Indo-European languages dominate most regions of northern Africa and western Eurasia, except for those regions of northern Eurasia settled during the Holocene by speakers of Uralic languages, originally hunter-gatherers. Many of these expansions, of course, took place in historical circumstances and are very well recorded. But the basic fact remains that the overall pre-AD 1500 distributions of both Afroasiatic and Indo-European, and probably Uralic too (except for Finnish and Hungarian), were laid down long before the days of Cheops, Sargon of Agade, Alexander the Great, Jesus Christ, or Mohammed. None of these people, or the religions associated with some of them, can be highlighted as prime movers.

Moving across to the opposite side of Eurasia and following the same logic, the Sino-Tibetan, Austroasiatic, Austronesian, Tai, and Hmong-Mien families would all have begun their dispersal from the region of rice and millet cultivation in central and southern China, focused in the middle and lower Yellow and Yangzi valleys, between 5000 and 2000 BC. Austronesians eventually colonized the greater part of the Pacific after 1500 BC, after migrating through Island Southeast Asia via Taiwan and island-hopping around much of western Melanesia, particularly New Guinea, where numerous Papuan language families have maintained dominance to the present as a result of indigenous developments in food production. The languages of northern tropical Australia probably reflect a deep Pleistocene ancestry, but the Pama-Nyungan language family that covers most of the continent beyond the tropics had a much more recent origin, and perhaps reflected the impact of new population arrivals from India or Indonesia around 4000 years ago, bringing dogs (dingoes) and a heavy emphasis on a backed and microlithic stone tool technology.

Across the Pacific, in the Americas, the Mayan, Otomanguean, Mixe-Zoque, Uto-Aztecan, and Chibchan language families probably spread as a result of agricultural developments in Greater Mesoamerica after 3500 BC. In South America the picture is a little more diffuse, but some of the major Andean and Amazonian families might have spread as a result of the widespread establishment of maize and manioc agriculture after about 2000 BC. Examples here include Quechua and Aymara in the Andes, and lowland Amazonian families such as Arawak, Carib, and Tupi.

Archeologically, these suggested language radiations associated with early agricultural societies should be reflected in the distributions of some very widespread archeological complexes. In particular, it has been noted in many regions that the archeological complexes of early agricultural phases are much more widespread and homogeneous in content than the highly regionalized complexes of later periods. This appears to be the case in some parts of early Neolithic Europe, East Asia, and the Pacific, and amongst the early formative cultures of the Americas. There is simply not space in this article to refer to all of this archeological evidence.

Indeed, the author freely admits that the above reconstructions are not universally accepted, as discussed in more detail elsewhere (see Bibliography). It should also be noted that disagreements are not just between disciplines, but also occur within them. For example, not all linguists or archeologists believe that Austronesian languages spread by migration from southern China through Taiwan (e.g., Donohue and Denham, 2010; see reply in Bellwood, 2011). There is also another powerful source of information on human prehistory, one not really acknowledged in this article, and this is human genetics and skeletal morphometrics. As I sit in front of my computer writing this article, yet another genetics article crosses my desk, by Irina Pugach et al., (2013), suggesting that gene flow occurred between northern Australia and India around 4000 years ago. Needless to say, the authors draw the same archeological conclusion as do I, that new populations arrived in northern Australia with their genes, their dogs, and a different (but not entirely unique) stone technology (they do not consider linguistics). This movement, if verifiable, had nothing whatsoever to do with agriculture. But, like that of the Athabaskan and Eskimo-Aleut hunter-gatherers of the North American middle and late Holocene, it had everything to do with economy and technology, and perhaps also a degree of geographical retreat by the earlier inhabitants of the territories that these groups entered. In the US Southwest, for instance, Apachean (Athabaskan) speakers entered former Pueblo territories after AD 1300 because the former maize farming inhabitants retracted their distributions in the face of drought, warfare, overpopulation, or all in combination. The Inuit Eskimo were able to colonize coastal regions of Arctic, Canada, and Greenland within the past millennium because their Paleoeskimo predecessors had virtually disappeared from these territories.

Language Contact and Cultural Contact

Finally, language and archeology correlations can be sought not only for the origins and dispersal histories of language families, but they can also reflect the contacts which took place from time to time between languages in different families and subgroups. For instance, the Austronesian speakers in pockets of coastal New Guinea have been in intense contact for upward of 2500 years with the speakers of Papuan languages in several unrelated families. This has led to a great deal of contact-induced change and language shift, and it is therefore not surprising to discover that distributions of material culture often cross-cut language boundaries. The archeological record, however, suggests that quite strong differences in material culture would have distinguished Papuan and Austronesian societies 3000 years ago, at the time of the Lapita archeological spread through much of the western Pacific. The Lapita spread, with its distinctive stamped pottery, lithic and shell artifacts, was probably associated with the initial Austronesian colonization of many of the western Pacific Islands. But it is significant that it appears initially to have avoided the island of New Guinea itself, where Austronesian speakers even today are found only in a few pockets of coastal distribution (Kirch and Green, 2001; note that late Lapita sites do exist in southeastern New Guinea).

Linguist Robert Dixon (1997) once suggested that the overall history of the major language families of the world

can be separated into short periods of widespread dispersal, when the families were actually founded through migration, interspersed with long periods like that described for New Guinea, when populations of quite different linguistic and cultural origin interacted over the long term, whether peacefully or belligerently. This hypothesis resembles the theory of punctuated equilibrium as applied to the biological evolution of species.

In this regard, not all of the speakers of some of the major language families are of tightly defined and geographically restricted genetic origin. For instance, the speakers of Austronesian languages range from Southeast Asians to Melanesians and Polynesians. The speakers of Indo-European languages range from northern Europeans to northern Indians. The speakers of Afroasiatic languages range from Ethiopians to Palestinians and Israelis. It is possible, but rather unlikely, that these differences represent no more than natural selection operating since the initial population dispersal which founded the language family in question. It is far more likely that they reflect population mixing, not always paralleled by an equivalent amount of language mixing. In other words, language families can have a life of their own, as can nodes of biological variation. Many population dispersals must have incorporated large numbers of the existing inhabitants of the newly settled regions, with consequent genetic effects stamped on later generations. This does not mean that there can be no correlations between variations in language and biology within our single and unified human species, but we must be aware that any correlations will not always be clear-cut and obvious. They must be teased apart with care.

Abstract

Approximately 7.5% of kindergarten children exhibit significant delays in language learning of unknown origin – a condition often referred to as language learning impairment (LLI). Children with LLI are susceptible for reading failure and other academic achievement difficulties, school dropout, as well as social and emotional problems. Here we provide a characterization of LLI on multiple levels, namely behavioral assessment, etiological models drawing on current psychological and biological domains, as well as remedial intervention. The article concludes with a brief synopsis of future directions regarding basic and applied research in LLI.

Early reports of children who failed to learn language at or near the expected age, but with no history of hearing loss, intellectual disability, acquired brain lesions, or developmental anomalies of the speech organs, date back to the late nineteenth century. English and French authors usually published their brief descriptions under the umbrella of 'congenital aphasia' or 'aphasie congénitale,' a phrase coined by deaf instructor Léon Vaïsse in 1866. The German literature used the designation 'Hörstummheit' (hearing mutism), introduced in 1886 by Raphael Coën, then a 'Spracharzt' (literally, 'speech doctor'). Based on extensive clinical observations, the speech doctors proposed etiological models and designed therapy programs for children with severe limitations in language output, laying the ground for further refinement and conceptual progress of the condition. In the 1950s, efforts in differentiating deficits in language production from those involving both comprehension and production resulted in the terms 'expressive developmental aphasia' and 'receptive–expressive developmental aphasia.' Partially motivated by the fact that the prefix 'a' classically denotes absence, the term 'dysphasia' (indicating difficulties in language) appeared in the 1960s, and 'developmental dysphasia' became the most frequent classification for language impairment of unknown origin about two decades later (Benton, 1978; Tallal and Piercy, 1978). However, none of these classifications succeeded as appropriately descriptive terminology. Over the years, several other phrases were created to describe the syndrome, such as 'deviant language,' 'delayed language,' 'developmental language disorder,' and 'specific language impairment,' all consistently emphasizing the developmental rather than acquired nature of the disorder as well as the specificity of the deficit to the linguistic domain. Problems in language acquisition secondary to other developmental disabilities, such as hearing loss or deafness, mental retardation, autism, evidence of neurological illness (such as seizure disorder or hemiplegia), and structural or motor deficits affecting the oral musculature (such as cleft palate or cerebral palsy), were traditionally excluded from the classification under consideration.

Although 'specific language impairment' has become a popular notion in the contemporary Anglo-American literature, several researchers prefer the most recent classification 'language learning impairment' (LLI), to acknowledge the results from longitudinal studies that demonstrate a continuum between early spoken and subsequent written language learning difficulties in children (Rissman et al., 1990; Snowling et al., 2000; Tallal et al., 1997). Empirical findings that point to neurobehavioral similarities between language impairment and reading disability (or 'developmental dyslexia') have further strengthened the broader LLI concept (cf Bishop and Snowling, 2004; Heim and Benasich, 2006). However, it is important to emphasize that while children with developmental language disorders often continue on to have literacy problems, this is not the case for all children. Furthermore, there are many children with dyslexia who do not appear to have had an early history of or concurrent oral language impairment. Thus, the classification of LLI (which we will use in this article) should not be taken to be synonymous with developmental dyslexia.

Disorders of language can occur for manifold reasons, and rank among the most prevalent of all developmental disabilities. It has been estimated that approximately 20% of kindergarten and school-age children suffer from deficits in oral and/or written language (Beitchman et al., 1986b; S.E. Shaywitz and Shaywitz, 2001). The most common known causes of language disturbances are hearing loss (including intermittent hearing loss resulting from chronic otitis media), intellectual disability, and motor or structural defects affecting the oral musculature. However, even when language disorders secondary to these other conditions are excluded, approximately 7.5% of kindergarten children exhibit significant delays in language learning of unknown origin (Tomblin et al., 1997).

Diagnosis

To date, there is no definitive neurological, genetic, or other biological marker of LLI that can be applied at the individual level to diagnose the condition. As such the differential diagnosis of LLI is based on behavioral evaluations that include audiological, neurological, psychological, educational, speech, and language, and in older children, literacy assessments. The *Diagnostic and Statistical Manual of Mental Disorders*, Fourth Edition, Text Revision (DSM-IV-TR; American Psychiatric Association, 2000) distinguishes between two basic categories of developmental language disorder in the context of otherwise

typical development: 'expressive language disorder,' principally affecting language production, and 'mixed receptive–expressive language disorder,' encompassing both language comprehension and production deficits. Comprehension and/or production problems may manifest within one or more of the components of language, including phonology (organization of speech sounds), morphology (inflectional and lexical word formation), semantics (meaning of language forms), syntax (phrase and sentence formation), and pragmatics (interactive conversational skills). Because psychometric measures of expressive and receptive language have not shown sufficient validity for making the distinction between these two forms of language impairment, and because individual children may change in the extent to which they show expressive and receptive problems across development, the forthcoming fifth edition of the DSM (DSM-5; expected release in May 2013) resigned the expressive versus mixed-language disorder category. Instead the designation 'specific language impairment' (SLI) along with the more general classification 'language impairment' (LI) has been proposed. The latter may be seen as synonymous with the term LLI, indicating that language learning disturbances, across development, generally affect both spoken and written language skills, may occur as a primary condition, or may coexist with other developmental disorders (cf Heim and Benasich, 2006). Accordingly, while many young children with LLI concurrently exhibit difficulties in the ability to clearly and correctly produce one or more of the sounds in speech, such articulation difficulties often occur in the absence of receptive or expressive language problems. Furthermore, many developmental cognitive disorders, such as intellectual impairment, autistic spectrum disorder, learning disability, central auditory processing disorder, as well as genetic syndromes, such as Down syndrome, Fragile X syndrome, Klinefelter syndrome, and Williams syndrome generally include delay in language development.

Children with LLI also have been found to be at risk for behavioral and emotional disorders, such as attention deficit hyperactivity disorder, anxiety, or depression (Beitchman et al., 1986a; Benasich et al., 1993; Tallal et al., 1989a). Moreover, LLI children are more likely to play alone and have lesser and poorer quality peer relationships. A recent longitudinal study suggests that behavioral difficulties (conduct issues and hyperactivity) in language-impaired individuals decrease to typical population levels from childhood to adolescence, whereas emotional problems are still present in adolescents with a history of LLI. In contrast, social (peer) difficulties become more prominent as these children grow older (St. Clair et al., 2011). Conversely, elevated occurrence rates of impaired language development have been observed in children receiving services for emotional and behavioral disorders (Benner, 2005; Benner et al., 2009).

Longitudinal research following children with LLI from the preschool through elementary school years has demonstrated a striking link between early oral language disturbances and subsequent academic achievement problems, especially dyslexia, which is characterized by reading, writing, and spelling deficits (Rissman et al., 1990; Snowling et al., 2000; Tallal et al., 1997). In line with this, family risk studies in dyslexia suggest that well-developed language skills help children to compensate for reading and spelling problems (Snowling et al., 2003, 2007). When comparing children classified as 'language impaired' with those diagnosed as 'dyslexic,' it becomes obvious that both groups are characterized by a variety of oral language deficits, specifically phonological processing and language comprehension difficulties (cf Bishop, 1997; Stark and Tallal, 1988). Impairments in these parameters of language do not always match, and different models exist to explain the overlap and distinction between the two disorders (cf Bishop and Snowling, 2004; Messaoud-Galusi and Marshall, 2010). It is still a matter of considerable debate, however, whether the relationship between oral language and literacy impairments derives from speech-specific mechanisms or from more basic neural-processing deficits (cf Heim and Benasich, 2006; Tallal and Gaab, 2006).

Etiology

Considerable attention has been focused on trying to understand the causes of LLI. Given the lack of homogeneity among children showing delayed language development, and the diversity of co-occurring symptomatologies, it is unlikely that a single etiology is responsible. Etiological research has been concerned with linguistic, perceptual/cognitive, genetic, and neurobiological mechanisms.

Linguistic Studies

There have been considerable advances made in understanding the specific linguistic deficits of children with language impairments. Particular patterns of difficulty have been observed within the linguistic components of phonology, morphology, and syntax. For instance, English-speaking preschool children with LLI omit tense-related morphemes (e.g., third person singular -s, past-tense -ed) more often than younger, typically developing children with a comparable mean length of utterance. Although the growing LLI child may demonstrate an increased use of these morphemes, some of these children still experience problems upon entering elementary education programs (cf Rice, 2004). Another area of difficulty and prolonged period of mastery is the correct use of English articles. Polite et al. (2011) found that 5-year-olds with LLI make less use of definite articles in particular, relative to younger, typically developing individuals. Furthermore, children with LLI tend to utter sentences of simpler syntactic structure and exhibit a weakness in comprehending complex sentences (cf L.B. Leonard, 1998). Pragmatic or social communication skills in LLI are usually of milder degree and less affected than the formal aspects of language (Tomblin et al., 2004). This is in contrast to children with autism spectrum disorder who generally exhibit more severe pragmatic and social communication deficits (both verbal and nonverbal) than do children with LLI.

Overall, children with LLI appear to develop the structures of language along a similar linguistic trajectory to that seen in younger children with typical language development, albeit considerably more slowly (Curtiss et al., 1992). To date, there is little evidence that the affected children produce linguistic errors that are deviant or substantially different from younger individuals matched for language status. Rather, LLI children

take much longer to progress through the stages of typical language development. Not all linguistic aspects in LLI, however, may show onset delays and protracted growth periods on the same timescale (cf Rice, 2004) and variations may also occur as a function of the severity of the disorder (Law et al., 2008).

Crosslinguistic research of childhood language disorders has failed to find common (universal) linguistic profiles across individuals struggling to learn different languages. Rather, the common feature of LLI crosslinguistically appears to be that whichever linguistic structures are acoustically brief, unstressed, or of weak phonetic substance, and occur less frequently in a particular language, are the most difficult for typical children to learn, and also the most delayed in individuals with LLI (cf L.B. Leonard, 1998). The apparent similarity in the order of linguistic development across populations and language environments gives strong support for a potent metric of sheer difficulty (whether representational or perceptual) that is imposed on the learning of linguistic structures and contents, and most vulnerable to language deficits.

Perceptual/Cognitive Studies

The most extensive etiological studies to date have utilized behavioral methodologies and have resulted in two classes of theoretical accounts: the 'linguistic specific' versus the 'domain general' account. The 'domain general' approach posits that general mechanisms (attention, sensory processing, sequencing, memory, executive functions) important for learning are at the core of the language learning deficits seen in children with LLI. A prominent exponent of the latter class is the 'rate processing constraint' hypothesis, which posits a direct impact of processing speed on learning in general. Because speech perception and comprehension require exquisite temporal resolution at high spectral accuracy over extended time periods (cf Hickok and Poeppel, 2007; Shannon, 2005), rate-processing constraints would be expected to particularly impact linguistic processing. In this view, central auditory processing constraints, specifically in the areas of auditory attention, sequencing, and serial memory, may result from a more basic impairment in the rate of neural information processing (cf Heim and Benasich, 2006; Tallal, 2004; Tallal and Gaab, 2006; Tallal et al., 1993). Tallal and colleagues have shown that many children with phonologically based speech, language, and reading disorders need significantly more neural processing time (hundreds of milliseconds instead of tens of milliseconds) to process rapidly changing sensory stimuli. They have hypothesized that this dynamic sensory constraint has a particularly detrimental effect on phonological processing because many acoustic cues occur in parallel and/or in rapid succession within syllables and words, which typically spans time windows in the tens of milliseconds range. It is important to note that if a child is poor at resolving the acoustic differences between phonemes, he/she likely will have great difficulty becoming aware that words can be broken into smaller units (speech sounds) and ultimately map onto letters and letter strings. This so-called 'phonological awareness' deficit is considered to be at the heart of reading impairments, including dyslexia (cf Melby-Lervåg et al., 2012). In addition to phonological processing and awareness, a lower level acoustic rate constraint has been shown to impact speech segmentation (McNealy et al., 2010) as well as the perception of short and unstressed grammatical forms, specifically grammatical morphology (Fellbaum et al., 1995).

In school-age children and adults with language-based learning impairments, enhanced dynamic auditory/visual sensitivity has been found to be linked to superior reading skills (Conlon et al., 2004; Helenius et al., 1999; cf Stein, 2001). Importantly, significant positive correlations between sensory processing rate and language/literacy skills have also been reported in unselected individuals from childhood to adulthood (Talcott et al., 2000; Walker et al., 2006). These findings provide strong evidence that individual differences in dynamic sensitivity across sensory modalities play an important role in the development of both oral and written language across the entire range of development. As such, children with language disturbances of unknown origin may fall at the disadvantageous end of a normal distribution, rather than representing a distinct impairment.

In addition to research being concerned with fine-grained acoustic analysis at the intrasyllabic level (in the tens of milliseconds range), other authors have focused on low-frequency temporal acoustic cues (on the order of hundreds of milliseconds). These acoustic cues, called 'time–energy envelopes,' are carried along with the phonological structure of syllables, and play a crucial role in speech rhythm identification, and thus in typical speech perception are important for processing prosodic cues in language. Several studies have posited deficits in acoustic processing of the time–energy envelope as a candidate mechanism underlying developmental language and reading disorders (Corriveau et al., 2007; Goswami et al., 2002; Richardson et al., 2004).

Constraints in the rate of processing have also been examined on a cognitive level, beyond perception. For instance, Miller et al. (2001) showed that school-age children with LLI exhibited about 14% slower response times than their typically developing peers on a wide array of tasks, some of which did not involve language, such as simple motor reaction, visual search, and mental rotation demands.

Processing limitations in working memory and executive function have also been postulated to account for the language deficits observed in LLI (cf Montgomery et al., 2010). In their seminal work, replicated by many other researchers, Gathercole and Baddeley (1990, 1993) observed that many children with LLI have great difficulty in repeating multisyllabic pseudowords. This has been attributed to impairment in phonological storage, affecting acquisition of vocabulary and grammar, as well as literacy achievement later in life. In a more recent study, L.B. Leonard et al. (2007) found that verbal working memory made a larger contribution to language performance than general processing speed.

The proponents of the 'linguistic-specific' hypothesis strongly dispute these data. They exclude any role for nonlinguistic processing constraints as a possible etiology for LLI. Alternatively, they support a modular view of language processing and propose that developmental language disorders are caused by failure of innate, 'language specific,' modules to function normally (cf L.B. Leonard, 1998; Pennington and Bishop, 2009).

Genetic Studies

LLI often aggregates in families (Flax et al., 2003; Tallal et al., 1989b, 2001; Tomblin, 1989), occurs more often in monozygotic than in dizygotic twins (Bishop et al., 1995; Tomblin and Buckwalter, 1998), and may be genetically transmitted (Bartlett et al., 2002, 2004; Monaco, 2007; SLI Consortium, 2002, 2004; Vernes et al., 2008). Infants born into families with a history of LLI are, thus, at an elevated risk for developing language/literacy impairments themselves. With the goal of identifying the developmental precursors to LLI, Benasich and colleagues (cf Benasich and Choudhury, 2012; Heim and Benasich, 2006) followed two groups of infants prospectively through the early school years: infants born into families with a positive history of LLI (FH+) and age-mates without such a family history (FH−). Using convergent methodologies at the behavioral and brain-electrical level (see Section Neurobiological Studies) the specific aim was to determine whether individual differences in perceptual/cognitive processing abilities, established in infancy, predicted subsequent language development and disorders. At age 7.5 months, FH+ infants tended to need longer processing times for nonverbal acoustic events than FH− controls. Follow-up measures indicated that two variables – nonverbal acoustic processing rate established at this early age and gender – correctly predicted over 90% of those children who at age 3 years scored within the 'impaired' range on the verbal (but not performance) scale of the Stanford Binet test of intelligence (Thorndike et al., 1986). In other words, those infants (particularly males) who exhibited the slowest auditory processing rates were subsequently most likely to be delayed in language development (Benasich and Tallal, 1996). Perhaps the most striking finding of this study, however, was that these data were independent of family history and thus clearly demonstrate the crucial aspect of sensory timing and gender (being male) for early language development. Moreover, when these children were followed into their early elementary school years, a toddler's rate of receptive (but not expressive) language development was found to be a significant predictor of subsequent reading skills (Flax et al., 2009). This is consistent with other studies demonstrating a link between early spoken language impairments and literacy delay (Catts et al., 2008; Snowling et al., 2000; Whitehouse et al., 2009).

The finding that LLI appears to run in families has also led to a number of molecular-genetic studies focusing on the search for specific genes that may be linked to the condition. Bartlett et al. (2002, 2004) collected extensive behavioral and genetic data on five multigenerational pedigrees of Celtic ancestry that segregate language impairment. A genome-wide categorical linkage analysis was conducted under both dominant and recessive models by use of three phenotypic classifications: clinical diagnosis of language impairment, spoken language test scores below the normal range, and substantial discrepancy between reading and nonverbal cognitive ability. Despite these pedigrees being selected based on spoken language impairment, significant linkages were found in a region of the long arm (q) of chromosome 13 (13q21), and only with the recessive reading discrepancy model. This result was confirmed in a North American sample selected according to the same phenotype criteria.

As mentioned earlier in this article, language delay is a core disability in autistic spectrum disorder, and those children with autism who do learn to talk often show language profiles similar to that of LLI children (Kjelgaard and Tager-Flusberg, 2001). Family studies have found that even in siblings and twins of children with autism who are not autistic, a disproportionate number experience language difficulties reminiscent of the phenotype of language impairment of unknown origin (Fombonne et al., 1997; Freeman et al., 1989; Szatmari et al., 1993). It is of considerable interest, therefore, that a significant linkage to chromosome 13q21 also has been found in a number of genetic studies of autism (Collaborative Linkage Study of Autism, 2001a,b). Furthermore, when families were subdivided by whether the autistic child and his/her sibling were concordant for presence or absence of phrase speech delay (defined as onset of phrase speech later than 36 months), the linkage signal on 13q21 was only increased in the speech-delayed group (Collaborative Linkage Study of Autism, 2001b). Intriguingly, the same genetic marker in both the LLI and autism studies yielded the highest linkage scores on this particular chromosomal region (Bartlett et al., 2004). These genetic studies provide strong evidence not only for a continuum between developmental language and reading disorders (Bartlett et al., 2002), but also a potential overlap with autism (Bartlett et al., 2004).

Neurobiological Studies

Over the past three decades, there has been a spurt in literature applying several electrophysiological and neuroimaging methodologies to the study of the neuronal correlates of LLI. Because a dominant role of the left hemisphere has been noted for both acoustic and linguistic functions that rely on high-temporal precision information processing (Schwartz and Tallal, 1980; Zatorre and Belin, 2001), neurobiological studies have specifically focused on hemispheric asymmetry in LLI. Results from magnetic resonance imaging (MRI) have indicated volume reduction in left-hemisphere language structures (such as the *planum temporale*) and/or absence of the typical leftward asymmetry in developmental disorders of oral and written language (Gauger et al., 1997; Herbert et al., 2005; Hynd et al., 1990; Plante et al., 1991). The issue of these digressions is not conclusive as there have been other contradictory observations (Preis et al., 1998; Rumsey et al., 1997). A promising approach is provided by a more recent MRI study, suggesting that LLI children with relatively smaller, symmetrical brain structures may show deficits across a wide range of language and reading functions, whereas those children with larger, more asymmetrical brain structures tend to exhibit less difficulty, with relatively preserved oral and written language comprehension (Leonard et al., 2006).

Functional MRI (fMRI) studies have been conducted mainly in school-age children and adults with a diagnosis of dyslexia rather than SLI. These have revealed a hypoactivation of left-hemisphere posterior regions during reading processes (Hoeft

et al., 2007; Shaywitz et al., 2002; Shaywitz et al., 1998; Temple et al., 2001). Affected individuals have also been found to show hyperactivation in anterior regions, such as the inferior frontal gyrus of the left and right hemisphere, which has been suggested to reflect compensatory mechanisms to overcome the disruption of posterior cortical networks (Georgiewa et al., 2002; Hoeft et al., 2007; Shaywitz et al., 2002; Shaywitz et al., 1998). In line with this, the strength of right prefrontal activity during a reading task taxing phonological awareness positively predicted dyslexic children's reading progress 2.5 years later (Hoeft et al., 2011). In a recent study, Raschle et al. (2012) reported that the posterior hypoactivation is already a characteristic in the prereading child at risk for developing language/literacy problems by virtue of family history. Furthermore, reduced posterior activity was accompanied by lower performance in an auditory phonological memory test, regardless of familial risk. This important result indicates that rather than being a consequence of lack of reading experience or brain reorganization due to reading difficulty, this distinctive pattern of hypoactivation of left-hemisphere posterior regions may be a neurobiological constraint on subsequent literacy development.

Electrophysiological techniques such as electroencephalography (EEG) and magnetoencephalography (MEG) have the advantage of providing temporal resolution most compatible with probing the real-time neural processing involved in language. In EEG work exploring the neuronal correlates of processing 'slow' temporal cues (hundreds of milliseconds) important for speech prosody, typically reading children had earlier and larger right-hemisphere responses, whereas poor readers exhibited dominant left-hemisphere activity. Electrocortical asymmetry contributed significantly to the variability in phonological awareness (Abrams et al., 2009). A similar finding has been obtained in adults with dyslexia, who showed impaired performance in phonological domains and decreased temporal stability of low-frequency magnetocortical responses in the right hemisphere evoked by slow modulations in nonspeech stimuli (Hämäläinen et al., 2012).

Electrophysiological studies probing the neural correlates of processing 'fast' temporal cues (tens of milliseconds) essential for tracking formant transitions in speech often show deviances in the left hemisphere of language/literacy-impaired individuals. Using MEG, the left-hemispheric sources underlying the magnetic wave around 200 ms after onset of a tone or syllable were found to be located more anterior in dyslexia children than in typical peers (Heim et al., 2000). This has been taken to indicate that the source positions might index activity within the *planum temporale* in the unimpaired children, whereas in the dyslexia children sources might be tied to sites anterior to the planum. When listening to brief and unstressed grammatical forms embedded in various language contexts, LLI children showed attenuated electrocortical responses from 200 to 400 ms after stimulus onset over left temporal sites, and enhanced responses over the right hemisphere. The processing pattern tended to be reversed in children with typical language development (Shafer et al., 2001). Such studies are suggestive of a reduced dynamic sensitivity in the posterior perisylvian region of the left hemisphere. As a consequence, less efficient cortical areas or sites might be recruited for auditory reception, contributing to the rate-processing differences observed in individuals with a history of language-based learning disability. More direct support for the 'rate processing constraint' hypothesis is provided by a recent EEG study evaluating high-frequency auditory oscillations evoked by fast-paced tone doublets (Heim et al., 2011). Oscillatory rhythms in school-age children with LLI did not differ from those in typically developing peers for the first tone, but negatively digressed in magnitude and temporal stability for the second tone of the doublet. Explanations for this pattern may include the fact that neural masses cannot be engaged in a well-synchronized and orderly fashion in LLI when rapid processing is needed. Alternatively, the recovery time of the cell assemblies firing to the first stimulus may be more variable in the LLI group, leading to greater latency jitter of the second response.

Divergences in brain-electrical processing patterns to rapid tone sequences have already been observed between 6-month-old infants with a family history of LLI and their age-mates from control families (Benasich et al., 2006; Choudhury and Benasich, 2011). The at-risk group exhibited smaller neuronal discrimination responses than the control group in the left hemisphere. Moreover, electrocortical parameters in the latency range around 250 ms after stimulus onset have been found to be predictive of language abilities at 16, 24, 36, and 48 months of age above and beyond family risk status. It may well be the case, however, that encoding deficits for fine-grained acoustic structures are already present on a subcortical level. By recording brainstem potentials to fast tonal sweeps, Basu et al. (2010) found the very early neural activity to be degraded in the majority of children comprising the LLI group. Similar evidence emerged from studies involving poor readers, showing weaker neuronal encoding of syllable fine structure than typically reading children (Banai et al., 2009; Hornickel et al., 2012). It remains to be determined whether and how such mechanisms ultimately contribute to other linguistic deficits associated with LLI.

Remedial Intervention

Remediation of LLI is generally provided by speech language pathologists, psychologists, or special education teachers. Traditionally, speech and language therapy has been guided by a detailed linguistic assessment of the pattern of receptive as well as expressive errors made by an individual child using both standardized testing instruments and language sampling methodologies. Remediation has focused on helping the child to use age-appropriate linguistic structures in a variety of contexts. In the literacy domain, intervention protocols have been concerned with explicitly training children to recognize and manipulate the speech sounds within words (called phonological awareness, see Section Perceptual/Cognitive Studies) in an attempt to improve reading decoding skills, as well as methods aimed at improving fluency and reading comprehension. Longitudinal research has shown that children with LLI generally require

approximately 2 years of traditional intervention to achieve the equivalent of 1 year of gain in oral and written language development (cf L.B. Leonard, 1998; Lyon and Moats, 1997). In a study monitoring the acquisition of grammatical morphemes by preschool children with LLI during intervention, L.B. Leonard et al. (2006, 2008) reported only modest gains, even after 96 sessions of treatment. Because the performance increases were steady and maintained 1 month after completion, the authors concluded that maturation may have had an important influence, suggesting an arduous and protracted acquisition process of grammatical morphemes. Other factors such as nonlinguistic skills may also have mediated the outcome. Drawing on research showing significant contributions of working memory and executive function to language performance, L.B. Leonard et al. (2007) recommended that intervention in LLI should be broad-based, concurrently training both linguistic forms and general information processing. Greater efficiency in information processing may help the affected child to better learn the targeted linguistic structures.

Electrophysiological studies of sensory cortices in animals have supported the notion that functional brain circuits are shaped by experience and can be altered through specific, temporally cohesive training regimens (cf Buonomano and Merzenich, 1998; de Villers-Sidani and Merzenich, 2011). This approach has led to the design of neuroplasticity-based remedies, which assume that the temporal precision of neural coding can be enhanced by intense training in an optimal learning environment. Merzenich and Tallal (Merzenich et al., 1996; Tallal et al., 1996) reported the results from the first series of controlled studies designed to test this hypothesis. Children with LLI worked on a set of computerized audiovisual training exercises, in which rapid transitions in speech and language were either presented with natural speech (control group) or speech that had been prolonged in time and differentially amplified (experimental group). As children in the experimental group progressed through the exercises and performance improved, the modified acoustic stimuli were presented at rates and amplitude levels closer and closer to those that occur in natural speech. In addition to the acoustically modified speech tasks, the experimental group engaged in an exercise designed to individually adapt to speed up their rate of nonlinguistic acoustic processing, while the control group performed another computer exercise that did not target processing speed. Both groups of children benefited significantly from intervention in speech discrimination and language comprehension. However, participants in the experimental group, who completed training with a focus on enhancing fine-grained acoustic analysis, exhibited not only an acceleration in auditory rate processing, but also significantly greater gains than the control group on measures of speech and language. Subsequent studies that implemented this form of neuroplasticity-based remedy in LLI revealed collateral improvements in the literacy domain, as well as changes in metabolic brain activity (Gaab et al., 2007; Temple et al., 2003; cf Tallal, 2004). Moreover, LLI individuals and typically developing children benefited from this training on measures of brain-electrical activity underlying selective auditory attention (Stevens et al., 2008). Using audiovisual training without linguistic material, Kujala et al. (2001) reported faster reaction times and enhanced electrocortical responses to sound changes in reading-impaired children. Importantly, the nonlinguistic training generalized to the level of reading decoding performance.

Overall, such remediation studies, together with those focusing on phonological awareness training (cf Snowling and Hulme, 2011), have stimulated intervention research that aims to develop more scientifically validated approaches for the treatment of disturbances in oral and written language learning. Several training programs (presented as computer games) have been designed and made commercially available to enhance perceptual, cognitive, language, and literacy skills in various age groups (Fast ForWord-Language and Literacy Series at http://www.scilearn.com/, Cogmed Working Memory Training at http://www.cogmed.com/, LearningRx at http://www.learningrx.com/). Crucially, for children without access to resources for intense, individualized speech therapy, computerized training programs have proven to be equally as effective as one-on-one speech therapy or academic enrichment provided for a comparable amount of time (Gillam et al., 2008).

Goals for Future Research

The brief overview presented here underscores the complexity of LLI, which involves multiple levels of analysis, ranging from the molecular level to overt behavior. It seems likely that the precursors of LLI can be observed very early in life, and also that language deficits persist, usually in subtle form, into later childhood, adolescence, and conceivably into adulthood. Children with LLI are susceptible for reading failure and other academic achievement difficulties, school dropout, as well as social and emotional problems. Therefore, the impact of LLI on society is substantive (cf Heim and Benasich, 2006). Future research should continue to focus on etiology, specifically on the neurophysiological, genetic, and environmental influences that contribute mutually to the condition. In this vein, research is underway aiming to characterize how nonlinguistic neural processes (attention, dynamic processing, memory, and other executive functions) interact developmentally with language systems in the brain – during typical and atypical language development. Prospective studies following infants at risk for LLI and control peers longitudinally into adolescence have shown particular promise to address these questions. Such studies are still few in number, however. Moreover, the integration of different levels of analysis, including cognitive methodologies, sophisticated neuroimaging and electrophysiological procedures, as well as molecular-genetic techniques will help to narrow down the candidate causal and contributory mechanisms for LLI. Determining whether LLI represents a distinct disability or rather lies at the disadvantageous end of a continuum of interindividual differences will also remain an important focus of research. The ultimate goal will be to achieve a theoretical understanding of the multiple factors affecting the language acquisition process. This may in turn lead to

the development of more effective training protocols for accelerating oral as well as written language learning in all individuals, specifically those with LLI.

This article is a revision of the previous edition article by J.A. Fishman, volume 12, pp. 8351–8355, © 2001, Elsevier Ltd.

Abstract

This article reviews the field of language policy, and presents a historical overview of the theoretical perspectives. It reviews the activities of classical language planning from the mid-twentieth century to the more critical and post-structural perspective of the field today. By presenting a framework of motivations for language policy, the article also presents different cases of types of language policy.

The field of language policy can be considered a branch of macro-sociolinguistics, also known as sociology of language. Not only has the field of language policy evolved in relation to changes in the social sciences, including sociolinguistics, and our epistemologies in the twenty-first century, but also the naming of the field itself has shifted. Originally scholars referred to the field as *language planning*, focusing on what could be done by the state to systematically promote linguistic change (Cooper, 1989; Fishman et al., 1968; Fishman, 1971; Haugen, 1959, 1966; Kaplan and Baldauf, 1997). Cooper (1989) defines language planning as "*deliberate* efforts to influence the behaviour of others with respect to the acquisition, structure, or functional allocations of their language codes" (p. 45, my italics). But post-structuralist and critical scholarship has challenged the idea that a community's way of speaking could be planned and changed by authoritative agencies. There are beliefs, practices, and even regulations that impact the ways in which people use language. Thus, the naming of the field itself has shifted to *language policy*, as it recognizes the multiple forces that influence behavior toward language (*LP*) (Ricento, 2006; Shohamy, 2006; Spolsky, 2004, 2012). Some scholars, however, have preferred to speak about *language policy and planning* (*LPP*) (Hornberger and Ricento, 1996; Hornberger, 2006) or *language policy and language planning* (LPLP) (Wright, 2004), suggesting that both terms are needed in order to capture their distinctive roles – one referring to language changes by the state or authoritative organizations, the other communicating behaviors and beliefs or attitudes toward language that shape the way that language is managed and used in society.

The Beginnings: Classic Language Planning

Language planning became an important field of study during the 1960s and 1970s, in what Ricento (2000: 206) has called *classic language planning*. Einar Haugen, a Scandinavian language specialist is credited with having used the term *language planning* for the first time in 1959 to refer to "the activity of preparing a normative orthography, grammar, and dictionary for the guidance of writers and speakers in a non-homogeneous speech community" (p. 8). The term itself was first used by Uriel Weinreich in a 1957 seminar at Columbia University (Cooper, 1989: 29).

In 1965 Joshua Fishman published his now classic article entitled "Who speaks what language to whom and when," the basis for the development of macro-sociolinguistics or sociology of language, which focuses on the social organization of language behavior, "including not only language usage per se, but also language attitudes and overt behaviors toward language and toward language users" (Fishman, 1972: 1). Fishman argued, and has continued to do so, that social action was needed on behalf of languages and its speakers, and that language could be planned just in the same way that there is economic planning.

Around the same time, in a study of Modern Norwegian, Einar Haugen defined language planning as consisting of four prongs: (1) norm selection, (2) codification, (3) implementation of language functions by spread, and (4) elaboration of functions to meet language needs (1966). Norm selection refers to the formal role that language was to have in society; for example, as an official or national language. Codification includes the choice of linguistic forms, including standardization and graphization. Implementation has to do with whether the policy would be accepted and followed. Finally, elaboration refers to continued linguistic reforms that have societal aims such as modernization, purification, and other stylistic reforms.

In 1968, Fishman, Ferguson, and Das Gupta published *Language Problems of Developing Nations*, perhaps what could be considered the first formal text in the field of language policy. It was the 'problems' of developing nations, and specifically the fact that national identity and national language did not coincide with either ethnic identity nor language use, that in many ways fueled the development of the field (Jernudd and Das Gupta, 1971). Language planning was put in the service of 'solving' the language 'problems' of the newly independent African and Asian states, by assessing the sociolinguistic situation and prescribing certain changes in how language was to be used (Das Gupta and Ferguson, 1977). Jernudd and Das Gupta (1971: 211) summarize the charge of language planning by saying that it is "a political and administrative activity for solving language problems in society." It is clear that these early language planners strongly believed in the social intervention of the state on behalf of languages and their users.

Language planning was originally studied as consisting of two types:

1. *Corpus planning* refers to changes in the linguistic form of the language itself through standardization (standardizing language forms), graphization (developing a writing system), and modernization (coining new words and terms).

2. *Status planning* refers to changes in the functions of language in order to elevate its prestige and increase the uses of a language.

These terms are attributed to the German sociolinguist, Heinz Kloss (1969).

Although described as two processes, Joshua A. Fishman insists that this distinction is clearer in theory than in practice, and that it is only possible to engage both types jointly (Fishman, 2006).

From the very beginning of language planning activities, there was questioning of whether language could indeed be planned, as reflected in the title of Rubin and Jernudd's influential early book, *Can Language be Planned?* (1971). The questioning of whether it was possible to definitely plan the form that a language takes, as well as its uses, emerged from the field itself. Einar Haugen had referred to the *ecology of language*; that is, to the "interactions between any given language and its environment" (1972: 57). Haugen defines that environment as being social and natural, in part psychological, and in part sociological. And he states: "The ecology of language is determined by the people who learn it, use it, and transmit it to others" (p. 57). By putting language in the hands of people and in the interactions between individual choices and socio-psychological possibilities and restrictions, deliberate language planning by governments and authoritative agencies takes a backward step, as the more flexible concept of language policy began to overtake the field.

From Language Planning to Language Policy

In 1989, Robert Cooper published his influential book, *Language Planning and Social Change*. With the now classic question, "What actors attempt to influence what behaviors of which people for what ends under what conditions by what means through what decision-making process with what effect?" (p. 98), Cooper changed the lens of language planning from one of mere description to one engaged in theorizing social action. Language planning, said Cooper, was not only in the hands of governments and authoritative bodies as the Académie Française, but also in the hands of individuals (like Ben Yehuda in the case of revitalization of Hebrew in Israel) and in the hands of communities and groups (such as women opposing sexist language). Cooper also introduced a third type of language planning, beyond corpus and status planning, that he termed *acquisition planning*. This type of language planning focuses on increasing the number of users of the language through two means: (1) the teaching of foreign/second languages, (2) the use of the home language as medium of instruction so as to spur language maintenance or to reacquire the language. Because of the importance of education in acquisition planning, Kaplan and Baldauf (1997) have called it language-in-education planning (LiEP), and many scholars refer to it as language education planning (Shohamy, 2006).

What is important about Cooper's contribution is that it expands the classical language planning activity. Beyond states and authoritative agencies, other agents are included as language planners, and the activity is not restricted to a single thing. As we cited in the introduction of this article, Cooper defined language planning as: "deliberate efforts to influence the behaviour of others with respect to the acquisition, structure, or functional allocations of their language codes" (p. 45). Cooper's definition talks about "influencing" linguistic 'behavior,' rather than changing it (since the activity may just modify or maintain behaviors). The emphasis in Cooper's work is on influencing behaviors and not on solving problems.

At around the same time James Tollefson (1991) published *Planning Language, Planning Inequality*. Interestingly enough, the subtitle of the book was *Language Policy in the Community*. In this important book, Tollefson advances a central idea in the shift from classical language planning to what we know today as language policy. He says:

> In this book language planning-policy means the institutionalization of language as a basis for distinctions among social groups (classes). That is, language policy is one mechanism for locating language within social structure so that language determines who has access to political power and economic resources. Language policy is one mechanism by which dominant groups establish hegemony in language use.
>
> p. 16

Tollefson points to the fact that language actions and choices are always constrained by ideological or structural (class) means, having to do with power, hegemony, and dominance. Structural constraints can block understanding of inequality, leading then to ideology. And he signals that language is an arena for struggle, since social groups exercise power through it. Tollefson adds: "Language policy is a form of disciplinary power. Its success depends in part upon the ability of the state to structure into the institutions of society the differentiation of individuals into 'insider' and 'outsiders'" (Tollefson, 1991: 207). Thus, Tollefson posits an alternative conception of language policy referring to both governmental and nongovernmental activity and focusing on the dynamic relationship between social structural relations and language practices that could result in structural equality. In keeping with Foucault's concept of governmentality, Tollefson views the operation of power as not limited to the state, but also to diverse practices.

Building on the critical work of Tollefson, and influenced by the work of Pierre Bourdieu, other scholars have maintained that all language behaviors and attitudes are always ideological and enmeshed in social systems of domination and subordination of groups, having to do not only with ethnicity, but also with class, gender, and race (Irvine and Gal, 2000). Bourdieu (1991) refers to habitus as a "system of dispositions common to all products of the same conditionings" (p. 59) by which the material form of life is "embodied and turned into second nature" (p. 63). This explains why speakers who do not control language practices that are considered 'standard' consider these to be more credible or legitimate than those they do speak. Language policy thus signals ideological positions and boundary markers of group identity for inclusion and exclusion (Kroskrity, 2000), and for constructing and effacing an other (Suleiman, 2004).

Power is said to operate in practices and ideologies and beliefs, and not only in laws and regulations. It is precisely these new understandings that have expanded the field of language policy from its original conceptualization as simply 'planning' at the state level and carried out by official language 'managers,' to one that today incorporates families,

faith communities, employers and educators (Spolsky, 2009). Spolsky points out (2009: 8):

> Many countries and institutions and social groups do not have formal or written language policies, so that the nature of their language policy must be derived from a study of their language practice or beliefs. Even where there is a formal, written language policy, its effect on language practices, is neither guaranteed nor consistent.

Thus, Spolsky (2004) expands our understandings of language policy to encompass three components:

1. *Language management* – also known as language planning, language intervention, language engineering, or language treatment, and referring to direct efforts to modify language practice beyond just government.
2. *Language practices* – the habitual pattern of selecting among varieties that make up the linguistic repertoire; that is, what people actually do.
3. *Language beliefs* or ideology – the values assigned to language and language use; that is, what people think should be done.

The first component, language management, was suggested by Jernudd (1993) to expand language planning from its emphasis on state as decision maker, to include more bottom-up and discourse-based planning. Jernudd (1997: 136) comments that language management includes:

> a broad range of different sociolinguistic situations at different levels of enlargement (from nation to firm), of a broad range of different interests and populations (from women to refugees), under widely different communicative circumstances (of media, channels, information processing), and foremost, of the different ideological and real, global and local sociopolitical conditions.

The variability of features inherent in language, the different ways in which language can be used at different times and with various interlocutors, as well as the various attitudes and beliefs held about language features and practices, is what makes language policy possible. Because choices must be made about all of this, either by individuals and groups themselves, or by outsiders, language policy has to be understood as a most important component of sociolinguistics.

Language choice and language beliefs are not neutral. As Pavlenko and Blackledge (2004: 1, 2) propose:

> [L]anguage choice and attitudes are inseparable from political arrangements, relations of power, language ideologies, and interlocutors' views of their own and others' identities. Ongoing social, economic, and political changes affect these constellations, modifying identity options offered to individuals at a given moment in history and ideologies that legitimize and value particular identities more than others.

Bringing the classical language planning strand together with the more flexible language policy strand, Shohamy (2006) points to the important distinction between 'overt policy' – having to do with the use of language to influence sociolinguistic use and norms, and thus social life – and 'covert or hidden policy' – not explicitly addressing language itself but relying on the discursive power of language to have the same social effects. Kaplan and Baldauf (1997) had already noticed that there has always been unplanned language policy and planning which goes unnoticed and unrecorded (p. 299). This has been the focus of Hornberger's work and especially of her important contribution on this topic – *Indigenous Literacies in the Americas: Language Planning from the Bottom Up* (1996). Hornberger's text and her use of the phrase 'bottom-up,' remind us that language policy does not always flow from the top-down. As Sutton and Levinson (2001: p. 3) have said, individuals and groups "engage in situated behaviors that are both constrained and enabled by existing structures, but which allow the person to exercise agency in the emerging situation." Thus, both the structure and the activity are parts of a complex process of dynamic construction in multiple directions and with multiple stakeholders. The line of power is not always linear from top to bottom since speakers have agency and language policy interacts with ideologies, global, national, and local forces. This more dynamic view of language policy, has spurred the recent focus on ethnographic studies of language policy (Hornberger and Johnson, 2007, Johnson, 2009; McCarty, 2011). These more grounded studies of language policy have taken a lens of language not as a system of structures, but of language as embodied practice, as interactions and practices, as languaging (Becker, 1995). Thus, language policy has taken up the attitudes, uses and management of languaging, and its pluralization, translanguaging (García, 2009). Translanguaging refers to the entire linguistic repertoire of bilingual people as they adjust their fluid discourse to different social, cultural, and political contexts, thus giving voice to new social realities.

Spolsky (2004) makes clear that if language policy takes on an ecological lens, two things follow:

1. Language policy must consider not just those language varieties that are recognized, but the entire sociolinguistic repertoire of the community.
2. Language policy cannot be considered except in relationship to the "social, political, economic, cultural, religious and ideological context that makes up human society" (p. 218).

But it is important to consider not only what language planning is and how it evolved, but also what have been the goals of the enterprise and why it is that this field has emerged and that these efforts have happened. We turn now to the goals and motivations for language planning, providing the context for some of the language policy efforts that we have been describing.

Goals and Motivations for Language Policy

Goals and motivations are different aspects of the same thing. Goals refer to what the action of language planning directs us toward. Motivation, however, is why we're impelled toward that goal. While classical language planning was more directed toward specific goals, the development of the field has emphasized how motivations are ideological and political. I first review the goals from a classical language planning perspective and then turn to how psychological and linguistic

motivations for language planning interact with socio-political and economic ones.

Goals: Linguistic and Social Goals

Nahir (1984) identified 11 goals for language planning:

1. *Language purification*, that is, maintaining linguistic consistency and standards of a language, usually through the development of prescriptive grammars and dictionaries.
2. *Language revival*, language revitalization and language reversal, encompassing efforts at restoring the language.
3. *Language reform*, that is, changing the orthography, spelling, lexicon, or grammar of a language in order to facilitate language use.
4. *Language standardization* for effective communication, accomplished usually through pedagogical grammars and dictionaries.
5. *Language spread*, an attempt to increase the number of speakers of a language, usually by having speakers shift to another language.
6. *Lexical modernization*, that is, expanding the capacity of a language to deal with new concepts and technology;
7. *Terminological unification*, also known as term planning, and having to do with development of equivalent terminology across geographic areas, especially terms having to do with medicine, science, industries, aviation and maritime navigation, and technology.
8. *Stylistic simplification*, attempts to make text more readable and less complex in lexicon and syntax.
9. *Interlingual communication* to facilitate communication between members of different speech communities.
10. *Language maintenance*, having to do with the preservation of a language.
11. *Auxiliary code standardization*. Here Nahir (1984) refers to "signs for the deaf, place names, and rules of transliteration and transcription" (p. 318).

All of these are important goals of the language planning enterprise and may be seen this way today. But what are the motivations for language planning? Why is it that these goals are pursued? What are the wishes and desires that motivate government, agencies, families, special groups, and individuals to pursue, adopt, or negotiate language policies? These questions are better answered by the scholarship of Joshua A. Fishman.

Motivations: Independence versus Interdependence

Fishman (2000, 2006) has pointed out that all efforts of language planning boil down to a super-factor of *independence versus interdependence*. By independence Fishman means whether the social group wants to be considered self-sufficient and autonomous of another. Interdependence refers to wanting to be affiliated with another social group. He develops a motivational theory for language policy that is divided into these two super-factors.

Language Policy for Independence

According to Fishman, *language policy for independence* is carried out through four processes: (1) ausbau, (2) uniqueness, (3) purification, and (4) classicization. Some of the cases that follow are from Fishman (2006), whereas others are from other sources, and especially from García and Fishman (2012).

1. *Ausbau*. This process builds on the work of Heinz Kloss (1967) who spoke about *abstandsprache* (language by virtue of linguistic distance) and *ausbausprache* (language by virtue of development). For Fishman the process of ausbau refers to language policy where the purpose is to build a language away from another; that is, to distance it from another. To contextualize this process, I provide the reader with some examples.
   a. Noah Webster developed the American English dictionary in 1783 as a way of distancing American English from British English.
   b. Urdu and Hindi adopted different scripts to differentiate one from the other. Hindi uses the Devanagari script, while Urdu uses a modified version of the Perso-Arabic script, with Nasta'liq the preferred calligraphic style. Although Hindi borrows strongly from Sanskrit, Urdu draws on Persian and Arabic.
   c. Norway has spurred several reforms in order to differentiate Norwegian from Danish. The result has been two written standards – Bokmål (book language) and Nynorsk (new Norwegian).
   d. In Central Asia the case of Azerbaijani/Turkish and Tajik/Farsi are important cases of *ausbau* by which languages that had been previously considered to be one language are now claimed to be autonomous from others, as they are linked to specific ethnic identities, thus claiming to be separate nations needing a state. For example, shortly after independence in Azerbaijan, the state language was first identified, in 1992, as 'Turkish' (türk dili). But there were also competing names proposed, 'Azerbaijani Turkic' and 'Azerbaijani.' In the 1995 constitution, the name 'Azerbaijani' was chosen. Thus, renaming the language emphasized the link between language and a separate Azerbaijani nationhood. Similarly, in Tajikistan, the 1989 language law referred to the language as 'Tajik (Farsi).' But in 1999 the word 'Farsi' was removed from the state language law, emphasizing separateness and autonomy as a nation of Tajikistan.
   e. This same process of ausbau has operated in the Slavic World (Hroch, 2010) by naming Serbian, Croatian, Bosnian, and Montenegrin, for example, when they were all previously considered Serbo-Croatian.
2. *Uniqueness*. Some language policy efforts aim to make a language more heavily one's own.
   a. Johannes Aavik (1880–1973) selected 'artificial' syllables for Estonian, ensuring that it would not be mistaken for Finnish or swallowed up by Russian.
3. *Purification*. This type of language policy is driven by fear of the language being contaminated. The first two examples have to do with languages, but the next two have to do with languaging; that is, the action of using language.
   a. The Loi Toubon in France that was passed in 1994 was meant to protect French from English. The law states: "By virtue of the Constitution, French is the language of the Republic, and the French language is a fundamental element of the character and heritage of France." As such, French is mandated in all official government

publications, advertisements, workplace, commercial contracts, and government-financed schools.

b. The promotion of Hebrew as a result of the revitalization that accompanied the formation of the state of Israel was accompanied by a ban on Yiddish, which was the language of most Ashkenazi Jews in the state. The Pure Language Society was set up in 1889 to stamp out Yiddish because of fear that it would contaminate the Hebrew of Israel.

c. The efforts of language academies such as the Académie Française and the Real Academia Española in the seventeenth and eighteenth centuries. This last one had a motto that said to "limpia, fija y da esplendor" (cleanses, stabilizes, and gives splendor).

d.The management of bad language, as with swearing or crude language, obscenities, profane language, blasphemy, racist, and sexist language.

4. *Classicization* refers to the policies that attempt to keep the language very close to its classical source. Examples follow:
   a. As explained in point 1, Hindi draws on Sanskrit, whereas Urdu draws on Arabic and Persian. Both languages attempt in this way to get closer to their classical source.
   b. Modern Tamil has attempted to shed Sanskrit loanwords in order to show continuity with its classical past as Old Tamil. This was the platform of the Pure Tamil movement of the early twentieth century.

Language Policy for Interdependence

In contrast to the four processes identified above, *language policy for interdependence* follows four different courses of action: (1) einbau, (2) internationalization, (3) regionalization, and (4) vernacularization. Again, examples are from Fishman (2006) and from García and Fishman (2012).

1. *Einbau*. This process is the opposite of ausbau. The language development is not meant to distance the languages from each other; instead, it brings them closer. There are many examples of this process:
   a. The Republic of Moldova declared itself independent in 1991 after the dissolution of the Soviet Union. The Language Law speaks of a Moldovan-Romanian linguistic identity, and little by little the few distinctions that once existed between Romanian and Moldovan are disappearing. Linguists and politicians have been acknowledging that the two languages are identical, although many continue to call their language Moldovan.
   b. Chinese authorities insist that the many languages spoken by Han Chinese are all 'dialects' of Chinese, despite the fact that they are all mutually unintelligible and could be considered different languages.
2. *Internationalization*. Some language policies are meant to bring language into compliance with the international community or as a focus of interest in the international community.
   a. Under the rule of Mustafa Kemal Atatürk, Turkish was westernized by adopting the Latin script, and adopting many French influences. In 1928, the Arabic-based Ottoman Turkish alphabet was replaced by the Latin alphabet. Afterward, a Turkish Language Association was established to replace loanwords of Arabic and Persian origin with Turkish equivalents.
   b. Although Kazakh, Kyrgyz, and Tajik are still written in Cyrillic, Azerbaijani, Turkmen, and Uzbek are written in the Latin alphabet, emphasizing their growing internationalization.
   c. The choice of the Latin script for the Oromo language in Ethiopia, as opposed to the Ge'ez used for Amharic and Tigrinya, has put Oromo in an internationalization path.
   d. The British Council and the US government have supported the greater use of English in international communication (Phillipson, 1992). The Goethe Institute, the Japanese Foundation, and the Instituto Cervantes do the same for German, Japanese, and Spanish, respectively.
3. *Regionalization*. Some language policies are meant to bring people from similar regions together.
   a. Bahasa Malaysia and Bahasa Indonesia derive from Bahasa Melayu (Malay) and despite their differences, borrow broadly from each other.
4. *Vernacularization*. Language policies that favor popular usage have the capacity to bring languages closer together.

But not all language planning has to do with choosing between independence and interdependence. Beyond the model proposed by Fishman (2006), we can identify motivations as stemming from three other supra-factors – exclusion, inclusion and cultural autonomy. I turn now to the ideological aspects of inclusion and exclusion that motivates language policy.

Motivations: Exclusion, Inclusion, and Cultural Autonomy

Seen from an ideological angle, language policies respond to three axes that have more to do with the speakers of a language than with language itself – exclusion, inclusion, and cultural autonomy.

Language Policy for Exclusion

When the motivation for language policy is exclusion, it is carried out through three processes:

1. *Shaming*. These language policies, often the result of language-in-education policies, result in stigmatization and exclusion of minority groups. They were prevalent in colonial contexts, and continue to be exercised in many states today.
   a. In Ghana, students who spoke African languages during colonial times were forced to wear a sign on their chest that said: "I'm stupid, I spoke a vernacular on the school's premises today."
   b. Indigenous children throughout the world are subjected to monolingual education policies with a purpose of shaming students who speak these languages. This is also the case of autochthonous minorities throughout Europe, of immigrant children throughout the world, and of other minorities. This shaming also includes those who speak varieties of language that are stigmatized, for example, African Americans in the USA.
   c. Until recently, Deaf children were educated through oralism which insisted on speech production and forbade them to use sign language.

   d. Latino students in the USA are often made to think that they speak a corrupted 'Spanglish,' when the translanguaging they perform is the discursive norm of all bilingual communities.
2. *Othering*. Language minorities today are not openly excluded from society and education with 'sticks.' Instead, other systems exclude those who do not conform linguistically.
   a. Students in the UK and the USA are excluded from educational opportunities when they do not do well in standardized examinations that test the use of standard English.
   b. Immigrants who do not speak the language of the state are excluded from citizenship opportunities by language tests. For example, the Dutch government requires that immigrant applicants take a Dutch language proficiency exam.
   c. In the UK and the USA, the use of standard English in education and assessment responds to a political ideology of monolingualism. In the UK, the Swann Report (1985) established policy that there should not be any 'separate provision' for language minority children and that bilingual education should not be supported. In the USA the No Child Left Behind Act requires states to assess student development of standard English.
3. *Silencing*. Language policy often attempts to silence other voices, erasing the power of people.
   a. Basing its dominance on its shape as a perfect hexagon, France has maintained that only French is tied to French identity. As a result, the other languages of France – Basque, Breton, Catalan, Corsican, German, Occitan, and Flemish – have been silenced until recently. The presence of regional languages in the regions where they are spoken was recognized by the French constitution (Article 75-1, 23 July 2008). Nevertheless, France's hesitation to ratify the European Charter for Regional or Minority Languages has to do with its fear to extend the expression of French identity to languages other than French.
   b. The banning of signing at schools for the deaf in the 1880s was motivated by an ideology that oral speech was the only way to pray to God, and thus, for deaf children to be saved.
   c. When Algeria obtained independence from France in 1962, it declared Classical Arabic the sole official and national language, rejecting Algerian Arabic and the Berber languages (also known as *Tamazight*).
   d. The Education Act of 1870 in Wales prohibited Welsh children from speaking Welsh at school, and required them to learn English.
   e. In the USA, California, Arizona, and Massachusetts have passed legislation banning bilingual education and the use of languages other than English as a means of instruction. And the word 'bilingual' has been silenced in all public discourse.

Language Policy for Inclusion

Even though most language education policy efforts have focused on exclusion of groups and peoples, we can also identify policies that do the opposite; that is, that include. *Language policy for inclusion* is carried out through three different means:

1. Bilingualism/multilingualism
   a. In Canada, the declaration of the Official Languages Act (1969), made English and French languages of Canadian identity.
   b. Singapore has adopted four official languages – Mandarin, Malay, Tamil, and English. The first three were chosen for identity purposes of the three major ethno-linguistic groups. And yet, these languages are mother tongues of only 17% of the Malay, Indian, and Chinese population. Malay is the mother tongue of 12% of Malays, Tamil of 5% of Indians, and Mandarin of .1% of the Chinese population (Rubdy, 2005: 57). English, however, was selected as a neutral 'other language' to serve as the language of interethnic communication.
2. Language teaching
   a. Some languages are taught to give advantage to people. This is the case especially of English throughout the world. In Africa, it is the case of Swahili in Eastern Africa, Wolof in Senegal, Akan in Ghana, Hausa in Northern Nigeria, and Lingala in Zaire.
   b. In some bilingual education programs, translanguaging is accepted as the norm of language practices in bilingual communities, and used to teach.
3. Diversity and pluralism
   a. In the 1970s and 1980s, many advocated for the use of nonsexist language, a use that is the norm today.
   b. In *Lau versus Nichols* (1974), the US Supreme Court ruled that educating English Language Learners in a language they did not understand was not equal educational opportunity and that something had to be done about the language of instruction.

Language Policy for Cultural Autonomy

Cultural autonomy refers to choices people make to be free "from domination by outsiders, not freedom to be independent" (García and Fishman, 2012: 143).

1. Since the Statute of Autonomy that was passed in 1979 after Francisco Franco's death, Catalan has been the only language used in the government of the *Generalitat de Catalunya* (the government), and must be used as medium of instruction, since it is the 'lengua propia' (own language) of the people. Since 1983, Catalonia has followed a policy of 'linguistic normalization' intended to protect and extend the use of Catalan.
2. In 1974 Québec declared French the sole official language of Québec, the language of Québecois identity, and Bill 101, the Charter of the French Language in 1977, made French the language of work, business, and education in Québec.

Conclusion

Depending on the ecological relationship between the social, historical, and political context and language, language policies act differently. The global world of today, with its interconnectedness made possible by technology produces different kinds of

language policies. Often the language policies are in conflict with each other, responding to the different wishes and motivations of sectors in society. The field has evolved from one where descriptions abounded and the state was in charge to one that is developing a theory of social action motivated by the struggle created by power and inequality. With a critical ethnographic lens, language policy is now equipped to teach us much about the ideological, socio-structural, and historical bases of language use, language attitudes, and language management.

Abstract

In this article, we report current data on language and communication disorders in the most frequent primary progressive syndromes of dementia, namely Alzheimer's disease, vascular cognitive impairment, and dementia with Lewy bodies. Language deficits are also the core features of three variants of primary progressive aphasia, namely the nonfluent/agrammatic, semantic, and logopenic variants. This survey reveals that, like other cognitive functions, language is highly vulnerable to delirium and neurodegenerative diseases. In some of them, language deficits result from impairment to linguistic processes per se. In others, they are the direct consequence of impairments affecting working memory and executive functions.

Introduction

Delirium is an acute state of confusion characterized by disturbances in consciousness and cognitive functioning. Although delirium is known to affect mainly attentional and perceptual abilities, language disturbances have also been reported. In clinical settings, delirium must be differentiated from dementia, a syndrome characterized by multiple deficits in cognition, which is the direct consequence of physiological changes. Dementia affects attention, perception, praxis, and higher mental functions such as episodic memory and executive functions. The core feature of dementia is impairment of memory, but specific language deficits as well as language difficulties caused by impairments of attention and/or executive functions are also found in the major forms of dementia. In this article, we briefly present the general characteristics of delirium and major forms of dementia. In each section, we also discuss disorders of language associated with each condition.

Language Processes in Delirium

Acute confusional state is used interchangeably with delirium and both conditions have been referred to as transient cognitive disorders. Delirium typically has a sudden onset, sharp rise, fluctuating course, and brief duration. Symptoms may arise abruptly (e.g., following a stroke or head injury) or can be gradual (e.g., in older adults receiving multiple medications). Reports on the onset and course of delirium are numerous and some have maintained that delirium is worse at night, a phenomenon known as sundowning (Evans, 1987). In general, delirium develops over periods of time that vary from a few hours to a few days. If left untreated, symptoms may last several days or weeks, even months, especially in individuals with coexisting cognitive disorders due to a persistent or evolving medical condition.

A number of conditions can cause delirium. The most common etiologies for delirium include chemical intoxication (e.g., alcohol intoxication and withdrawal), metabolic disorders (e.g., hypoglycemia), structural brain diseases (e.g., vascular infarction), infections (e.g., anticholinergic), and environmental factors (e.g., prior recent acute-care hospital admission).

Current diagnostic criteria for delirium are more commonly based on the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision* (DSM-IV-TR) (American Psychiatric Association, 2000). The DSM-IV-TR criteria focus on three essential features of delirium: disturbances of consciousness (i.e., reduced awareness of the environment) with reduced attention (Criterion A); a change in cognition or the development of a perceptual disturbance that is not accounted for by a preexisting, established, or evolving dementia (Criterion B); and a disturbance that develops over a short period of time and fluctuates over the course of the day (Criterion C). Criterion D refers to etiological features of delirium.

Delirium is ordinarily associated with changes in sleep–wake patterns, disorientation to time and space, disordered or incoherent speech, visual hallucinations, and marked alterations in psychomotor activity. Individuals suffering from delirium commonly display neuropsychological deficits in tasks involving attention and concentration, memory, language, and spatial processes. Evidence suggests that spatial and executive impairments are key features of delirium (Inouye et al., 2006).

Chédru and Geschwind (1972) provided one of the first descriptive studies of cognitive disorders in delirium including speech and language. These authors reported that impaired reading, writing, and verbal fluency were the most common linguistic abnormalities in delirium. They also determined that individuals suffering from delirium exhibited naming and repetition abnormalities but that spontaneous speech was relatively preserved. In 1994, Wallesch and Hundsalz compared a group of individuals suffering from delirium with a group diagnosed with probable Alzheimer's disease (AD) on naming and language comprehension tasks. They found a comparable number of naming errors in both groups but unrelated naming errors were significantly more frequent in the delirium group. These authors also showed that some of the overall unrelated naming errors in participants presenting with delirium were caused by visual misperceptions, thus supporting nonlinguistic influences on language.

A number of studies have found writing deficits in participants presenting with delirium. Macleod and Whitehead (1997) have shown that writing is the most impaired of the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.54031-8

language modalities in delirium. In a 6-month study, they compared the performance of a small group of individuals diagnosed with acute delirium with that of a control group. Their results provided further support for the predominance of writing impairments in delirium, which are mainly characterized by motor agraphia and the reduplication of letters. They also showed that reading was the least impaired of linguistic functions. Aakerlund and Rosenberg (1994) also found that all individuals who developed postoperative delirium had severely impaired writing, with features such as reluctance to write, motor disability, and spatial disturbances. Their results suggest that assessment of writing ability might be useful in the diagnosis of delirium.

Language Processes in Dementia

Diagnostic classifications of dementia syndromes identify various subtypes based on characteristics such as typical symptoms at presentation, progression and course of the disease, psychiatric and behavioral features as well as presumed causes (e.g., general medical condition, persistent effects of a substance, multiple etiologies). Because of the absence of biological markers or simple diagnostic methods, early detection of dementia relies on various assessments performed to rule out other possible causes and identify specific aspects of a disease (i.e., differential diagnosis). Neuropsychological testing plays an important role in the assessment of individuals with cognitive impairment. A large number of studies have sought to identify neuropsychological features that distinguish the different forms of dementia. What emerges from this work are descriptions of cognitive functioning, which contain some distinctions that are useful for the differential diagnosis of dementia. For example, there are remarkable differences between patients with AD and vascular cognitive impairment (VCI) with respect to long-term verbal memory and executive functions. However, these patients may present with similar language, constructional ability, attention, and memory deficits. Moreover, overlap in cognitive deficits is often seen between syndromes, possibly due to the heterogeneity of neuropsychological manifestations in the early stages of the disease (e.g., Benedet et al., 2012), as well as methodological problems, including the application of diagnostic criteria, selection of neuropsychological tests (aimed at large cognitive domains instead of more precise components of cognition), and lack of adequate matching of patients on age and education. In addition, the definition of dementia continues to evolve and recent criteria have made it possible to distinguish between different presentations of primary progressive aphasia (PPA).

With respect to language impairments, neuroepidemiological and neuropsychological studies propose clinical linguistic profiles usually associated with common forms of dementias. Recent neuropsycholinguistic studies have also made a major contribution to better characterization of language deficits in dementia by specifically identifying functional localization of impaired and preserved processing components and subcomponents of the linguistic processing system.

In the following sections we will review current data on language and communication disorders in the most frequent primary progressive syndromes of dementia, namely AD, VCI, dementia with Lewy bodies (DLB), as well as three forms of PPA, namely the nonfluent/agrammatic variant (nfvPPA), semantic variant (svPPA), and logopenic variant (lvPPA). The more salient characteristics of language disorders in these diseases are presented in Table 1.

Table 1 Salient characteristics of language disorders in the major forms of dementia

Language production	*Language comprehension*	*Reading*	*Spelling*	*Semantics*
1. Alzheimer's disease (early and moderate stages of the disease)				
Anomia	Deficit for words Possible deficit for sentences	Surface dyslexia	Surface dysgraphia	Access deficit and/or degraded semantic representations
2. Vascular cognitive impairment[a]				
Anomia	Deficit for sentences	Acquired dyslexia not specified	Acquired central dysgraphia Possible peripheral dysgraphia	Access deficit and/or degraded semantic representations
3. Dementia with Lewy bodies				
Anomia	Deficit for sentences	Unknown	Unknown	Access deficit and/or degraded semantic representations
4. Nonfluent/agrammatic variant of primary progressive aphasia				
Anomia Apraxia of speech Agrammatism	Deficit for syntactically complex sentences	Preserved in the early stages	Deep dysgraphia Agrammatism	Unimpaired
5. Semantic variant of primary progressive aphasia				
Anomia	Deficit for words	Surface dyslexia	Surface dysgraphia	Degraded semantic representations
6. Logopenic variant of primary progressive aphasia				
Anomia Impairment in repetition of long and complex sentences Phonological errors	Deficit for sentences	Phonological dyslexia	Phonological dysgraphia	Unimpaired

[a]Language deficits in vascular cognitive impairment generally depend on the location of prior strokes or white matter lesions.

Language Processes in AD

McKhann et al. (2011) recently revised the classification criteria for dementia due to AD. The diagnosis of probable AD requires that an individual present with a dementia syndrome established through a combination of history-taking from the patient and a knowledgeable informant as well as an objective cognitive assessment performed with a screening test or a neuropsychological assessment battery. The authors also differentiate between two types of AD presentation, according to the most prominent cognitive deficits. In the amnestic form, the most common presentation of AD, the deficits mainly include impairment in learning and recall of recently learned information. In the nonamnestic form, patients may present with prominent visuospatial (visual agnosia, prosopagnosia, simultagnosia, and alexia), executive function (impaired reasoning, judgment, and problem solving), or language (word-finding problems) deficits. This represents a major evolution from previous criteria where only the amnestic subtype of AD was considered.

Similar to other dementing syndromes, AD does not begin with global impairment in cognitive functions but usually progresses through different stages. The most pervasive characteristic of AD is undoubtedly progressive episodic memory loss associated with a decline in other cognitive areas. With respect to language, the typical course of AD is characterized mainly by: (1) word-finding problems in the early stages of the disease, (2) severe reduction, stereotyped utterances, important anomia, agraphia, and comprehension difficulties in moderate stages of the disease, and (3) impairment of all linguistic abilities in the severe and final stages. By using cognitive models of language processing, neuropsycholinguistic studies have significantly contributed to the identification of deficits affecting specific linguistic abilities in AD.

According to these studies, the main impact of the disease is on semantic memory, a component of explicit long-term memory that contains permanent information related to objects, concepts, words, and their meanings. Because of its central role in the processing of language, the deficit affecting semantic memory leads to substantial difficulties in word comprehension and production. Therefore, when tested with comprehensive batteries of language tests, individuals with AD usually show a poor performance in various tasks such as picture naming, word–picture matching, and semantic questionnaires, even in the early stages of the disease. Moreover, the consistency for individual items across tests (Hodges and Patterson, 1995; i.e., the same items are preserved or impaired across tests) and the consistency of impairment (Hodges et al., 1992b; i.e., the same deficit is observed in production and comprehension using visually and verbal-based materials) are suggestive of a deterioration in semantic representations instead of impaired access to preserved semantic representations (Rogers et al., 2006). This question is controversial, however, and other researchers have reported experimental data that tend to support a normal organization of semantic memory and an impaired ability to consciously retrieve items from the semantic network, at least in early stage AD (e.g., Rogers and Friedman, 2008). The relative preservation of superordinate knowledge as compared to specific and distinctive knowledge (e.g., knowing that a zebra is an animal but not that it has stripes or lives in Africa) is also suggestive of a partially degraded semantic network, combined with a deficit of explicit retrieval (Duarte et al., 2009). Furthermore, with respect to semantic memory, studies have also investigated whether the semantic loss in AD affects some categories more than others. Most of these studies conclude that individuals with AD perform worse on biological concepts (animals, fruits, vegetables, etc.) than on artifacts (vehicles, furniture, tools, etc.) (e.g., Garrard et al., 2001).

Articulatory, phonological, and syntactic abilities are usually considered unscathed until the final stage of AD. Some studies, however, showed that disease progression might impact these abilities. For example, Croot and her colleagues (Croot et al., 2000) have shown that in less typical cases of AD, phonological and articulatory abilities may be impaired, sometimes as a selective deficit. Syntactic processes required for sentence production (e.g., Bates et al., 1995) and sentence comprehension (e.g., Waters and Caplan, 1997) may also be compromised in some cases of AD, even in the early stages of the disease. Whether this deficit is really syntactic in nature or is more explicable in terms of a working memory disorder or in terms of semantic interpretative processing remains unresolved.

Studies on reading and writing impairments in AD also reflect a relative lack of consistency in findings. According to the standard clinical portrait of AD, reading and spelling abilities are considered largely preserved in patients, even at rather advanced stages of the disease. In contrast to this classical conception, several single-case and group studies using cognitive neuropsychological or parallel-distributed-processing models have shown that the ability to read aloud and to spell words is frequently affected in AD. These patients often demonstrate characteristics of surface dyslexia and surface dysgraphia: they are better at reading/spelling orthographically regular than irregular words (i.e., words with exceptional or unpredictable sound-to-spelling and spelling-to-sound correspondences), they show a preserved ability to read/write nonwords, and they tend to produce regularization errors in reading (e.g., bread → brid) and phonologically plausible errors in spelling (e.g., crane → crain). Group studies, however, have shown that different patterns of written language impairment may be observed in AD, especially according to the progression of the disease (Forbes et al., 2004; for a review on agraphia, see Neils-Strunjas et al., 2006; for a review on alexia, see Noble et al., 2000).

Language Processes in VCI

Recently, Gorelick et al. (2011) provided a new statement about vascular contributions to cognitive impairment and dementia, according to which VCI "represents the spectrum of cognitive impairment associated with frank stroke, vascular brain injury, or subclinical disease ranging from the least severe (i.e. vascular mild cognitive impairment) to the most severe (i.e. vascular dementia; VaD) clinical manifestations" (p. 2676). VCI may result from an array of causes. It includes all dementias following ischemic or hemorrhagic cerebrovascular accidents, i.e., single vascular insult (most typically to a critical area of the brain), repeated cerebral infarction (also referred to as multi-infarct dementia), and chronic ischemia without discrete infarction. According to Gorelick et al. (2011),

a diagnosis of probable VaD requires: (1) the demonstration of a loss of cognitive ability, associated with imaging evidence of cerebrovascular disease; and (2) the absence of a history of gradually progressive cognitive deficits before or after the stroke that suggests the presence of a nonvascular neurodegenerative disorder.

In contrast with the extensive literature on language deficits in AD, less is known about the patterns of cognitive deterioration in other forms of dementia. Consequently, the identification of clear neuropsychological differences between the major progressive dementias remains difficult to establish. In VCI, for example, most of the reported descriptions related to cognitive deficits concern behavioral manifestations and large cognitive domains. The most commonly reported cognitive impairments in VCI are bradyphrenia (slowed cognition), dysexecutive symptoms (e.g., difficulty in problem solving and planning), and decreased initiation and spontaneity. There are very few studies that have systematically described language disorders in VCI. Most of them were conducted in an attempt to differentiate VCI from AD. Many of these studies suggested that there was no significant difference in language function between the two syndromes (e.g., Fahlander et al., 2002). However, contradictory results were reported by other authors. For example, some reported that patients with VCI performed better than individuals with AD in picture naming tasks (Barr et al., 1992), while others found no differences between groups (Graham et al., 2004b) or the opposite pattern (Lukatela et al., 1998). With respect to semantic processing, individuals with VCI appeared to be more affected than those with AD (Graham et al., 2004a). Controversial results were also reported with respect to syntactic processing in VCI. According to most studies, the comprehension of complex sentences is affected in people with dementia because of impaired working memory and executive functioning. In some of these studies (e.g., Vuorinen et al., 2000), there was little or no difference in syntactic comprehension between individuals with AD and VCI, while in others (Grossman et al., 1996), individuals with VCI performed better than those with AD.

To date, very little is known about the nature and prevalence of reading and writing deficits in VCI. A few recent studies that included reading and writing tasks in the neuropsychological assessment found that both abilities appeared to be impaired in VCI. For example, using the Clinical Dementia Rating scale in newly diagnosed patients, Chan et al. (2008) found more reading difficulty in VCI than in AD. Other studies, however, found no differences between the two groups in reading tasks (Vuorinen et al., 2000). For written spelling, a few investigations (Forbes and Venneri, 2003) are suggestive of peripheral impairments (e.g., difficulty in writing letters and copying sentences). Others found that, as compared to individuals with AD, patients with VCI produced more spelling errors and grammatically less complex sentences, therefore suggesting a central origin to the deficit (Graham, 2000).

Finally, as compared to AD, the spontaneous speech of individuals with VCI is less empty and conveys more information but they tend to produce shorter and less grammatically complex phrases (Powell et al., 1988). The same authors have also shown that patients with VCI often present with abnormal prosody and articulation.

Language Processes in DLB

DLB is a frequent form of dementia, commonly regarded as a Parkinson-plus syndrome that has the clinical and pathological features of both AD and Parkinson's disease. In 2005, a DLB Consortium revised the criteria for the clinical and pathologic diagnosis of DLB (McKeith et al., 2005). According to these criteria, the central clinical diagnostic feature of DLB is the presence of dementia, as well as deficits on tests of attention, executive function, and visuospatial ability whereas memory could remain unimpaired, at least in the early stages of the disease. Two of the following three core features are sufficient for a diagnosis of probable DLB: (1) fluctuating cognition with pronounced variations in attention and alertness, (2) recurrent visual hallucinations that are typically well formed and detailed, and (3) spontaneous features of Parkinsonism. Moreover, the presence of one or more suggestive features (e.g., severe neuroleptic sensitivity) can reinforce the diagnosis of DLB.

There are few papers on the cognitive symptoms of DLB (e.g., Tröster, 2008). Most of them conclude that these symptoms are not specific to the disease. DLB is associated with impairment in all areas of cognition, with visuoperceptual/spatial deficits predominating. Almost no study has specifically addressed language deterioration in DLB. Language is usually considered unimpaired in the early stages of the disease but impairments in confrontation naming have been reported with progression. This impairment is considered similar to what has been observed in patients with AD (e.g., Lambon Ralph et al., 2001), while some authors (e.g., Ferman et al., 2006) have reported that picture naming is better preserved in DLB than AD and could therefore be used as a differential diagnosis feature. Lambon Ralph et al. (2001) have shown that semantic impairment is affected in AD and DLB. However, while patients with AD showed equivalent deficits in every modality, patients with DLB demonstrated more severe deficits when they were presented with pictures than with words, a performance interpreted by the authors as the result of a combination of semantic and visuoperceptual impairments. Individuals with DLB also present syntactic impairment in sentence comprehension, a deficit attributed (Gross et al., 2012) to working memory and executive dysfunctions. A similar executive origin was proposed to explain their difficulty in organizing narrative speech in both production (Ash et al., 2011) and comprehension (Ash et al., 2012) modalities. Finally, very little is known as yet about reading and spelling abilities in DLB.

Language Processes in PPA

PPA is a progressive disorder of language associated with atrophy of the frontal and temporal regions of the left hemisphere, typically resulting from a neurodegenerative disease. PPA is a heterogeneous condition, in which the most prominent clinical feature is a difficulty with language (progressive impairment of language production, object naming, syntax, or word comprehension), while other cognitive domains are not affected at onset and in the early stages of the disease (Mesulam et al., 2012). A broad ranging International Consensus Group recently published recommendations for

the diagnosis and classification of PPA (Gorno-Tempini et al., 2011). These recommendations provide a classification of PPA and its three main variants, namely the nfvPPA, svPPA, and lvPPA. In the following subsections, we will briefly review current data on language and communication disorders in these three variants of PPA.

Language Processes in nfvPPA

According to the classification proposed by Gorno-Tempini et al. (2011), at least one of the following two core features must be present to detect nfvPPA: (1) effortful, halting speech with inconsistent speech sound errors and distortions (apraxia of speech), and (2) agrammatism in language production. Moreover, at least two of the following three additional features must be present: (1) impaired comprehension of syntactically complex sentences, (2) spared single-word comprehension, and (3) spared object knowledge. Imaging abnormalities in the left posterior frontoinsular region support the diagnosis.

Patients with nfvPPA complain of difficulty expressing themselves and finding words (Ash et al., 2010). Their speech fluency remains relatively preserved in the early stage of the disease, although the spontaneous speech of some patients is markedly slow, hesitant, and effortful (an example of spontaneous speech is presented in **Figure 1**). As the disease progresses, speech fluency decreases and articulation and prosody become more affected. Thus individuals with nfvPPA may present apraxia of speech, sometimes as initial symptoms of the disease, characterized by deficits in motor planning and sequencing of speech movements. These deficits are responsible for the production of phonological errors as well as the slow rate and abnormal pauses in connected speech (Wilson et al., 2010). The second core feature for the diagnosis of nfvPPA is the presence of agrammatism in production, characterized by difficulty in inflecting verbs (Thompson et al., 2012), by the omission or substitution of closed-class words (Ash et al., 2010), and by difficulty in sentence construction involving embedded clauses (Deleon et al., 2012). Patients with nfvPPA may also present with deficits in comprehension of syntactically complex sentences (Peelle et al., 2008), while single-word comprehension is usually unimpaired. Finally, less is known about written language in nfvPPA. Reading abilities usually remain good, although in some patients the disease progression is accompanied by the production of phonological errors (Rohrer et al., 2010). Written production appears to be more impaired than reading, affecting the majority of patients. Frequently reported manifestations of dysgraphia involve written agrammatism and the production of non-phonologically plausible paragraphias (Sepelyak et al., 2011).

Language Processes in svPPA

The svPPA is a clinical syndrome that results from a degenerative disease of the temporal lobes, leading to the selective impairment of semantic memory. According to the classification proposed by Gorno-Tempini et al. (2011), the following two core features must be present to establish a diagnosis of svPPA: (1) impaired confrontation naming, and (2) impaired single-word comprehension. Moreover, at least three of the following additional features must be present: (1) impaired object knowledge, particularly for low-frequency or low-familiarity items, (2) surface dyslexia or dysgraphia, (3) spared repetition, and (4) spared speech production (grammar and motor speech). With respect to neuroimaging, svPPA is supported by the presence of abnormalities in the ventral and lateral portions of the anterior temporal lobes bilaterally, although damage is usually greater on the left.

Spontaneous speech in patients with svPPA is fluent, well articulated and grammatically correct but presents many signs of word-finding difficulties (see **Figure 1**): miscarried sentences, latencies, circumlocutions, and occasional semantic paraphasias (Hodges et al., 1992a). Repetition is typically well preserved for words, nonwords, and sentences (Hodges and Patterson, 2007). Patients usually complain of a loss of memory for words. This deficit is obvious in tests of naming to definition and confrontation naming in which patients mainly produce semantic errors consisting of the production of a superordinate (lion → animal) or a category coordinate (lion → tiger) concept. This pattern of errors reflects a loss of attribute knowledge along with preservation of general superordinate information (Hodges and Patterson, 1995). Patients are also impaired on tests of verbal and nonverbal semantic memory. Spoken and written single-word comprehension is affected in tasks of word–picture matching, synonymy judging, word sorting, etc. The centrality of the semantic deficit is also confirmed by tests exploring nonverbal semantic knowledge such as tests of semantic relatedness judgment on pictures, picture sorting, etc. Deficit in picture naming and single-word comprehension is influenced by the familiarity of the items in the early stage of svPPA, and extends to more typical concepts with the progression of the disease (Hodges and Patterson, 2007). Whether the semantic deficit in svPPA has a greater effect on some category of concepts or some type of words is also discussed in the literature. For example, category-specific semantic impairment is rarely observed in svPPA but individuals have been described with greater impairment for living than for nonliving things (Barbarotto et al., 1995). In some patients, performance was better for abstract than for concrete concepts (Macoir, 2009) but the reverse dissociation was also shown (Hoffman and Lambon Ralph, 2011). Syntax processing is considered preserved in svPPA but impairment in verb inflection has been reported in a few studies (Cortese et al., 2006), suggesting a semantic contribution to morphological processing. Reading and spelling impairments are other clinical features of svPPA. Patients demonstrate surface dyslexia and surface dysgraphia characteristics (Brambati et al., 2009). A strong association between these impairments and the extent of the semantic loss was demonstrated in word reading (e.g., Funnell, 1996) and word spelling (e.g., Macoir and Bernier, 2002).

Language Processes in lvPPA

The lvPPA was recently identified as a distinct form of PPA. The two core features essential to the diagnosis of lvPPA are the presence of anomia in spontaneous speech and confrontation naming, and impaired repetition of sentences and phrases (Gorno-Tempini et al., 2011). At least three of the following additional features must be present: (1) production of phonological errors, (2) preservation of semantic memory, (3) preservation of articulation and prosody, and (4) absence of

1.a Narrative discourse of a patient with nfvPPA

When asked to describe the "Cookie Theft picture" from the BDAE (Goodglass and Kaplan, 1983) (a boy is falling from a stool while trying to catch cookies. His mother wipes the dishes while the sink is flooding), GC a 63 year-old woman with nfvPPA answered: '*There's…there's a b-b-boy…there's waber…the the floor'*. This is all she produced with over 120 seconds. Sentences were short. Language was non-fluent, effortful and marked by phonological paraphasias.

1.b Spontaneous written description of the problems encountered in everyday life by SC, a patient with svPPA (Bier and Macoir, 2010)

I can prepare and eat all my meals very well . . . However, I've lost many words related to things that I eat. For example, when I want to eat spaghetti, I know how to prepare it: to make the sauce and the whole meal. Visually, I know what I have to put into it to make it. However, I don't remember all of the words that correspond to what I need . . . The only words I remember since I made the recipe 4 days ago are: two cans of tomatoes, one can of tomato juice, rice, beef, pepper, and a dozen other small things I can see in my head. I don't remember their names but I know where they are in my kitchen . . . It's when I go to the restaurant that my symptoms are obvious. When I read the menu, I don't understand anymore. It is only what I eat regularly in two restaurants, that I can recognize instantly when I read [the menu]. But if I go back to a restaurant after many months, I don't remember the name of what I ate, even when I read the menu.

1.c Sentence repetition in a patient with lvPPA

DG, a 74 year-old women with lvPPA performed flawlessly in a single-word (e.g., grocery; pelican; chocolate) and short sentence (the plane was gone; the sun shines in the sky) repetition task. However, her performance was substantially affected (incomplete sentences, omission or substitution of words, no response) when she was asked to repeat long and syntactically complex sentences.
Examples:

Stimulus: We will give her as soon as she will claim it
Response: We, we, … if she wants it

Stimulus: The chicken was eaten by the big black dog
Response: the dog and the chicken … I don't know

Bier, N., Macoir, J., 2010. How to make a spaghetti sauce with a dozen of small things that I can not name: a review of the impact of semantic memory deficits on everyday action. Journal of Clinical and Experimental Neuropsychology 32 (2), 201–211.

Goodglass, H., Kaplan, E., 1983. The Assessment of Aphasia and Related Disorders. Lea & Febiger, Philadelphia.

Figure 1 Examples of language deficits in the three variants of primary progressive aphasia.

agrammatism. With respect to neuroimaging, measures of cortical thinning have revealed a predominant left posterior perisylvian or parietal atrophy in individuals with lvPPA. This variant is highly reminiscent of posterior forms of conduction aphasias and has been shown to harbor underlying AD pathology.

Spontaneous speech of patients with lvPPA is slowed, with frequent word-finding pauses and production of phonological errors. Compared to nfvPPA, utterances are simple but grammatically correct, and motor control of speech is not affected. Confrontation naming is less impaired than in the semantic variant, and semantic processing is well preserved. Although repetition is spared for short single words, patients encounter substantial difficulty repeating long and complex sentences (see **Figure 1**), particularly low-probability ones for which word substitutions are noted, suggesting that patients use a semantic rather than a phonological route to repeat (Gorno-Tempini et al., 2008). This impairment in repetition is not linguistic in nature but rather attributed to a reduction in verbal short-term memory resources. A similar functional origin was proposed to account for the impairment in sentence comprehension also found in lvPPA patients (Amici et al., 2007), whose performance was influenced by length but not by syntactic complexity. With respect to syntactic and morpho-syntactic processing per se, individuals with lvPPA show neither a deficit in production of verb tense nor problems in the production of grammatical sentences in connected speech (Thompson et al., 2013). To our knowledge, only Brambati

et al. (2009) specifically explored reading abilities in lvPPA. Results from this study show a pattern of phonological dyslexia, characterized by severe impairment in reading nonwords, accompanied by mild impairment for regular and irregular words, suggesting a deficit mainly localized in the grapheme-to-phoneme conversion route of reading. According to Faria et al. (2013), patients with lvPPA usually present with phonological dysgraphia, characterized by an impaired phonology-to-orthography conversion route and partially impaired access to orthographic word forms. The same spelling profile was also reported in a majority of cases by Sepelyak and her colleagues (Sepelyak et al., 2011), although the authors noted that other forms of dysgraphia are also possible.

Conclusions

In this article, we briefly reviewed impairments of spoken and written language processes accompanying the major forms of primary progressive dementia as well as VCI. These deficits are often prominent symptoms of the disease and may occur early in the process. We have shown that substantial information is available for spoken language disturbances in AD as well as in nfvPPA and svPPA. In contrast with the extensive literature on these dementing illnesses, relatively little is known about the patterns of spoken language deterioration in VCI and DLB. For example, the few available descriptions of cognitive deficits in these diseases mainly concern behavioral manifestations and large cognitive domains. More specific abilities are almost completely ignored and it is still difficult to relate functional deficits to language components. The concept of lvPPA is also quite recent and further research is needed to complete the linguistic description of the syndrome.

Knowledge about written language deficits in the major forms of dementia and PPA, and their contribution to the overall language syndrome are much less established in the literature. For example, very little is known about written language in nfvPPA and lvPPA and, to the best of our knowledge, no authors have addressed reading and spelling abilities in DLB. Further research should address this linguistic domain in order to complete the clinical profile of the different syndromes and thus provide additional features for the differential diagnosis.

The concept of dementia continues to evolve and this was recently reflected in 2011 by an avalanche of new criteria for various syndromes. Current studies have refined core features and made it possible to distinguish between different forms of PPA, for example. An improvement in clinical diagnosis should result from the study of more specific subcomponents of the different cognitive domains. In this respect, cognitive neuropsychology is certainly useful in that it allows the fractionation of many cognitive domains into specialized subcomponents that can be selectively impaired in a neurological affection. Such an approach has led to extensive descriptions of language deficits in AD and svPPA. Further research is needed to better characterize the effect of the progression of the disease on various language abilities and components. Overall, better characterization of language deficits in dementia and PPA would also be very useful for behavioral treatment approaches, as well as for counseling and educating patients, families, and caregivers.

Abstract

Functional imaging has now been used to study the neurobiology of language for more than 20 years. In this article, we review the current literature from functional magnetic resonance imaging in the areas of phonological processing, word comprehension, sentence processing, and discourse comprehension. While this literature confirms a major role of the classical perisylvian regions of the left hemisphere in language processing, it has become increasingly apparent that there are important contributions to language processing from a wide network of brain areas, including many regions in the right hemisphere, sensory–motor regions, and other areas – particularly in the nonperisylvian regions of the temporal and parietal lobes. Of particular recent interest has been the role of sensory and motor cortices in semantic representation and the integration between verbal and nonverbal information during communication.

Introduction

Functional magnetic resonance imaging (fMRI) has become a widely used method to investigate the neurobiology of language. The major advantage of fMRI, particularly with respect to earlier methods such as positron emission tomography and single-photon emission computed tomography, is that it is completely noninvasive, requires no radiation exposure, and if performed correctly, is without serious risks. Furthermore, the images it produces have a very high spatial resolution (as detailed as 1 mm). Besides the confined space of an MRI scanner, which makes it difficult to perform certain types of tasks in MRI experiments, functional MRI studies require that the person being scanned remain relatively motionless, rendering certain research paradigms more difficult to use in fMRI studies. For example, overt language generation tasks are infrequently used in such studies, since they can engender significant head movement. When fMRI studies involve covert language production or passive reading or listening, it is not possible to measure the behavior of participants directly. Instead, researchers often perform separate investigations outside of the scanner to collect behavioral data that can be related to the imaging data. This solution, while introducing confounds of its own, is often preferable to using procedures that introduce head motion, require metalinguistic processing, or add extraneous motor or sensory tasks to the primary task of interest (Small and Nusbaum, 2004).

Stimulus paradigms commonly used to elicit behavior in fMRI experiments fall into three general categories: block designs, event-related (ER) designs, and more recently continuous narrative designs. In a block design, two or more conditions are alternated in blocks, with each block containing many stimuli (and possibly responses) of a consistent type. The duration of each block is typically less than 1 min and depends on the time it takes for the MRI scanner to acquire a single volume of data (usually the same as the repetition time, or TR, with a duration of 1.5–3 s). For example, if a block lasts for 20 s and the TR = 2, then there will be 10 functional brain volumes collected per block. Stimuli in a block are presented sequentially and consist of a single experimental condition repeated continuously for the duration of the block. By alternating blocks containing different conditions, the fMRI signal can be compared across conditions, yielding information about the functional anatomy of the behavior tested. In some cases, one condition includes only a visual fixation point or nothing at all, and the other condition(s) can be compared to this 'rest,' yielding a widespread pattern of brain activity in the 'active' condition when compared to the 'rest' condition. Another type of design includes two 'active' conditions that differ in minor ways, such that the 'subtraction' (statistical contrast) is thought to represent a 'cognitive element' of interest. This latter approach has come under some scrutiny in recent years, due to a number of probably fallacious assumptions of this 'subtraction' method (Amaro and Barker, 2006; Logothetis, 2008; Small and Nusbaum, 2004). The main advantage of the block design is the very high signal-to-noise ratio obtained by repeating the same stimuli over and over (Buxton et al., 1998; Friston et al., 1999). This approach has some important drawbacks, however, such as the sensitivity of the signal to drift (e.g., head motion) and, perhaps most importantly, the consequences for behavioral aspects of the study, including the inability to characterize the processing of a single stimulus at a time, to randomize different types of stimuli, and to avoid strong expectations (e.g., list monitoring effects).

In contrast to block designs, ER designs involve presentation and measurement of individual stimuli. In such experiments, stimuli of different types are typically presented in a pseudorandom order. Two different types of ER experimental designs are commonly used, slow and rapid. In slow ER experiments, stimulus presentation is followed by a sufficiently long interstimulus interval (ISI) to allow the brain's hemodynamic response (the basis of the blood oxygen level-dependent signal that underlies the fMRI signal) to rise and fall completely in response to the stimulus. It typically takes about 4–8 s for the hemodynamic response to reach its maximum (depending on responsive brain areas and stimulus intensity) and another 5–10 s for it to return to baseline (Friston et al., 1999; Katwal et al., 2012; Thompson and Siegle, 2009). The advantage of this slow ER design is that each individual stimulus response is clearly distinguishable and subject to individual analysis. The disadvantage of the slow ER design is that there are very

 http://dx.doi.org/10.1016/B978-0-08-097086-8.54033-1

few stimuli that can be presented, given the excessive time devoted to each one. On the other hand, combinations of individual events can be easily compared to rest or to other combinations of events in a variety of ways, taking advantage of individual features of the events.

To increase the numbers of stimuli presented in any given study, a number of researchers developed the 'rapid' ER design (Buckner et al., 1998; Burock et al., 1998; Maccotta et al., 2001; Wager et al., 2005), in which the individual stimuli are presented in relatively rapid succession, but separated by a variable ISI (or 'jitter') that permits mathematical separation of the overlapping hemodynamic responses. Both types of ER designs make it possible to analyze the brain effects related to individual trials, and when subjects are asked to make explicit responses to each stimulus, the trials can be evaluated with respect to different response characteristics (e.g., reaction times, errors). Other advantages include the possibility of randomizing the order of stimulus conditions (Rosen et al., 1998) and decreased sensitivity to head motion artifacts (Huang et al., 2002). The main drawback of ER designs is that the statistical power is lower than in block designs due to the fact that the signal change following a signal stimulus presentation is small.

Finally, some investigators have been experimenting with continuous narrative designs, in which naturalistic stimuli, such as movies or audiovisual stories, are presented for a relatively long duration, without any requirement by the subject other than attention to the stimulus. Each stimulus is coded beforehand for stimulus events of interest, e.g., hand movements (Hasson et al., 2004; Skipper et al., 2009) or semantic categories (Huth et al., 2012; Cukur et al., 2013), and then various methods are used to extract ER information from the raw times series. Although quite novel, this approach to stimulus presentation allows for the investigation of language in a real-world context without metacognitive influences.

Main Findings from fMRI Studies of Language Processing

Phonological Processing

Phonological processing involves detecting and discriminating differences in speech sounds for the purpose of speech understanding, and in producing the appropriate sounds in speech production. Various tasks have been used to investigate phonological processing, including repetition of words and syllables (Calvert et al., 1999; Riecker et al., 2000; Wildgruber et al., 2001), discriminating syllables or letters (Belin and Zatorre, 2003; Hugdahl et al., 2003; Jancke et al., 2002; Jancke and Shah, 2002; Jessen et al., 1999; Joanisse and Gati, 2003; Sekiyama et al., 2003), reading pseudowords that are pronounceable but have no meaning (Kotz et al., 2002; Mechelli et al., 2000; Meyer et al., 2002; Poldrack et al., 1999), discriminating pseudowords from real words (Binder et al., 2000; Cappa et al., 1998; Herbster et al., 1997; Hickok et al., 2003; Hugdahl et al., 2003; Meyer et al., 2002), judging whether words rhymes with each other (Booth et al., 2002; Buchanan et al., 2000; Heim and Friederici, 2003; Scott et al., ;2003), and recalling letters (Bunge et al., 2001; Burton et al., 2000, 2001, 2005; Burton and Small, 2006; Cohen et al., 1997; Hautzel et al., 2002; Rypma et al., 1999).

By way of introduction, it is important to note that the literature on 'phonological processing' contains a bewildering array of different phonological tasks, and that brain activation in the service of such 'phonological processing' depends critically on the task (Poeppel, 1996). In this section, we survey the frontal, parietal, and temporal regions involved in a variety of task-dependent phonological processes.

Frontal and Parietal Regions

A number of cortical regions in the frontal and parietal lobes appear to be involved in aspects of phonological processing. The frontal regions include the Rolandic operculum, the lower precentral gyrus, the gyral area directly ventral to the termination of the central sulcus (the 'guenon,' Bouchard et al., 2013), the dorsal part of the pars triangularis of the inferior frontal gyrus (IFG), and the junction between the orbital part of IFG and the middle frontal gyrus (MFG).

Among these regions, the guenon, ventral precentral gyrus, and Rolandic operculum appear to be involved in sensory–motor control during phonological processing (Vigneau et al., 2006). The upper guenon is in proximity to the primary motor area for the mouth and might contribute to low-level aspects of speech motor control. Several studies have found that this area is also activated during auditory discrimination of syllables (e.g., Hickok and Poeppel, 2004), listening to syllables (Wilson et al., 2004), and syllable production (Wildgruber et al., 2001). These findings suggest that simulation of motor activity might be necessary for perception of syllables (but see Tremblay and Small, 2011). The ventral part of the precentral gyrus is recruited by tongue and laryngeal movements (Riecher et al., 2000) and may be dedicated to coordination of fine movements of the pharynx and tongue (Poldrack et al., 1999) as well as working memory for phonological information (e.g., Bunge et al., 2001; Hautzel et al., 2002). The Rolandic operculum is activated in syllable/pseudoword articulation (Heim et al., 2002) and may reflect sensory–motor integration.

Previous studies have found that the pars opercularis is involved in phonological processing (Jessen et al., 1999; Mechelli et al., 2000; Sekiyama et al., 2003). This area appears to be important for working memory and/or cognitive control (Novick et al., 2005; Snyder et al., 2007) and is active on such tasks as recall lists of letters or syllables after a short delay (Bunge et al., 2001; Cohen et al., 1997; Hautzel et al., 2002; Rypma et al., 1999), and it might play an important role in executive control (Fuster, 1998). For example, in Snyder et al. (2007), participants performed a semantic and a phonological judgment. In each task, they were asked to select which of two targets best matched a probe. Both tasks included low-conflict and high-conflict trials. The results showed that the posterior left IFG showed increased activation with high versus low inhibition demand, regardless of whether the task was semantic or phonological. The anterior part of MFG and the pars triangularis of IFG are activated in syllable counting (Poldrack et al., 1999) and syllable identification (Sekiyama et al., 2003). The pars triangularis of the IFG and SMG are thought to be connected by the arcuate fasciculus (Catani et al., 2005) as well as by short connections (Duffau et al., 2003). Co-activations have been found in both pars triangularis and SMG during working-memory tasks (Cohen et al., 1997; Hautzel et al.,

2002; Rypma et al., 1999) and SMG might be related to phonological storage. The connection between the pars opercularis and the SMG suggests a frontal–temporal loop for phonological information retrieval and manipulation based on task demands. Finally, the anterior insula is recruited by dichotic presentation of syllables (Jäncke and Shah, 2002) and rhyme detection for written words (Booth et al., 2002).

Taken together, these findings suggest that the frontal and parietal regions are involved in the sensory–motor integration, retrieval, and manipulation of phonological information.

Temporal Regions

The temporal regions involved in phonological processing include primary auditory regions (within the lateral fissure and comprising parts of Heschl's gyrus and the superior temporal gyrus (STG), including planum polare and planum temporale (PT)), the anterior and middle parts of the STG, the middle part of the middle temporal gyrus (MTG), and the posterior part of the inferior temporal gyrus (ITG). These temporal regions are segregated along the superior temporal sulcus (STS).

Findings from nonhuman primate studies indicate that primary auditory regions consist of several parts (Hackett et al., 2001). A core field is comprised of auditory area I, rostral area, and rostrotemporal area with independent parallel inputs from the ventral division of the medial geniculate complex. The core field is surrounded by a belt field that consists of several areas, such as the caudolateral auditory belt, the caudomedial auditory belt, the anterior lateral auditory belt, and the rostrotemporolateral auditory belt. Anatomical tracing studies in monkeys found connections projecting from the anterior belt to the ventrolateral prefrontal cortex and from the caudal (posterior) belt to the dorsolateral prefrontal cortex. This provides evidence for ventral and dorsal processing streams within the auditory cortex (Kaas and Hackett, 2000). The dual processing streams in the auditory cortex are also found in the human brain. Anterior regions of the superior temporal cortex respond to native speech sounds and intelligible speech hierarchically, indicating an antero-lateral gradient along which the complexity of stimuli increases, from tones to words and sentences, while the posterior regions of the superior temporal cortex (e.g., PT) are involved in the processing of spectro-temporally complex sounds (for a review, see Rauschecker and Scott, 2009).

Recent fMRI studies have found that the anterior STG and Heschl's gyrus are involved in selective attention to sounds (Jäncke et al., 2001) and are activated in rhyming tasks (Fernandez et al., 2004). Regions in the left mid-posterior STS are found to perform phonetic and phonological analysis during speech perception (Turkeltaub and Coslett, 2010). The posterior STG is involved in phonological processing, independent of semantic processing. For instance, Graves et al. (2008) used an auditory pseudoword repetition task and found significantly reduced neural activity in the left posterior STG. This suggests that the left posterior STG participates specifically in lexical phonology. PT and posterior STG are connected with the precentral gyrus and pars opercularis of the IFG by the arcuate fasciculus (e.g., Parker et al., 2005). PT is involved in syllable perception (Jäncke et al., 2002; Joanisse and Gati, 2003; Sekiyama et al., 2003), auditory selective attention (Hugdahl et al., 2003), and covert speech production (Buchsbaum et al., 2001; Hickok et al., 2003; Okada et al., 2003). In speech perception and production, the PT and posterior STG in the temporal lobe, and the precentral gyrus and frontal operculum in the frontal lobe, are activated together. These findings are consistent with the (revised) motor theory of speech perception (Liberman and Whalen, 2000) and suggest a perception–action cycle permitting motor-sound-based phoneme representation (Rauschecker and Tian, 2000).

Semantic Processing of Words

Semantic processing of words is typically investigated by single word reading or listening (Binder et al., 1996, 2000; Cohen et al., 2002; Fiez et al., 1999; Moore and Price, 1999; Small et al., 1996; Specht and Reul, 2003), semantic categorization judgment (i.e., making a decision whether a presented stimulus is a member of a specific semantic category, such as living versus nonliving, or natural versus artificial (Binder et al., 1996, 2003; Braver and Bongiolatti, 2002; Buchanan et al., 2000; Heim et al., 2002; Noesselt et al., 2003; Poldrack et al., 1999; Scott et al., 2003), semantic association judgments involving words (Adams and Janata, 2002; Booth et al., 2002; Chee et al., 2000; Davis et al., 2004; McDermott et al., 2003; Noppeney and Price, 2004; Vandenberghe et al., 1996) or pictures (Adams and Janata, 2002; Chee et al., 2000; Vandenberghe et al., 1996), word generation (Buckner et al., 2000; Crosson et al., 1999), semantic retrieval (i.e., producing an object property) (Heun et al., 2000; James and Gauthier, 2004; Kelley et al., 2002; Thompson-Schill et al., 1999), and semantic priming (i.e., examining how the exposure to a stimulus influences the semantic processing of a later stimulus) (Kotz et al., 2002; Wagner et al., 2000; Wager and Smith, 2003).

Frontal Regions

In the frontal lobe, the pars orbitalis of the IFG appears to be important for online retrieval of semantic information (Demb et al., 1995). This region is involved in semantic categorization (Adams and Janata, 2002; Binder et al., 2003; Braver and Bongiolatti, 2002; Buchanan et al., 2000; Noesselt et al., 2003; Noppeney and Price, 2004; Poldrack et al., 1999), semantic retrieval (Kelley et al., 2002; James and Gauthier, 2004; Jobard et al., 2011), word generation (Adams and Janata, 2002; Gurd et al., 2002; Kelley et al., 2002; Wagner et al., 2001), and semantic association (Adams and Janata, 2002; Booth et al., 2002; Gurd et al., 2002; McDermott et al., 2003). The roles of the pars triangularis and pars opercularis of the IFG in semantic processing are controversial. Poldrack et al. (1999) found that performance of a semantic decision task preferentially elicited the ventral aspect of the left IFG (pars orbitalis/pars triangularis), and performance of a phonological task activated the dorsal part of the IFG (pars triangularis/pars opercularis). The authors claimed that the pars opercularis was relatively selective for phonological processing, whereas the pars triangularis was more relevant for semantic processing. However, recent findings and meta-analysis results have indicated that the pars opercularis appears to play a role in semantic functions,

whereas different portions of the pars triangularis may play various roles, with the dorsal part more involved in phonological processing and the ventral part more involved in semantic processing (Vigneau et al., 2006).

Parietal and Temporal Regions

In the parietal and temporal lobes, several brain regions are found to be involved in lexical–semantic processing, including the angular gyrus (AG), MTG, and ITG. All these areas are commonly activated during comprehension of spoken and written language (Price, 2012; Spitsyna et al., 2006).

Angular Gyrus

AG has been shown to be involved in the semantic processing of written words (Booth et al., 2002), auditory words (Ahmad et al., 2003; Chee et al., 1999), and pictures (Seghier et al., 2010). The anatomical location of AG adjoins visual, spatial, auditory, and somatosensory association areas, and this region plays a role in complex information integration and knowledge retrieval. Some researchers claim that AG might be the best candidate for a high-level, supermodel integration area in the human brain (Geschwind, 1965). It is possible that AG is at the top of a processing hierarchy for semantic retrieval and integration (Binder et al., 2009). A recent fMRI study investigated the functional subdivisions of the left AG for semantic processing and for default mode processing (Seghier et al., 2010). Their findings showed the middle AG to be involved in semantic association regardless of stimuli, and that this region overlaps with parts of the 'default network' (for an introduction to the default network, see Anticevic et al., 2012). Dorsal AG was primarily involved in meaning access of visual stimuli, and ventral AG was involved when making semantic judgments on visual stimuli.

Middle and Inferior Temporal Gyri

Activation in MTG and ITG occurs during semantic judgments (e.g., whether a target word is semantically related to a probe word) on auditory words, written words, and pictures. The anterior parts of MTG and ITG appear to be involved in retrieval and integration of semantic information independent of input modality (e.g., Awad et al., 2007; Jobard et al., 2007). The posterior MTG is sensitive to increased working-memory load, and processing word meaning from auditory and visual modalities simultaneously (Dick et al., 2009; Holle et al., 2010; Kircher et al., 2009; Robins et al., 2009).

Fusiform Gyrus

The fusiform gyrus (FG) is involved in word reading and word listening, when studied in contrast with pseudoword reading and nonword listening (Fiebach et al., 2002; Moore and Price, 1999, but see McCandiss et al., 2003). FG plays an important role in semantic processing of both pictures and words. Previous studies have found that anterior FG responds specifically to word meaning and the semantic context in which the words are presented, while posterior FG is activated during recognition of object pictures (e.g., Ishai et al., 1999; Okada et al., 2000; Haxby et al., 2001). FG also becomes active during reading in different modalities, such as tactile and visual in blind and sighted subjects (Büchel et al., 1998). Nobre et al. (1994) claimed that conceptual knowledge of words might be accessed directly in the inferior temporal lobe. FG is thought to correspond to the 'basal temporal language area' described by Lüders et al. (1991) based on neurophysiological recordings in epilepsy patients. The FG and parahippocampal gyrus are often activated together during semantic processing, and this suggests an interface between semantic memory (e.g., memory about conceptual knowledge) and episodic memory processing (Levy et al., 2004).

Connectivity

A classic model of frontal–temporal connections is the Broca–Wernicke–Geschwind model (Geschwind, 1970). According to the model, the arcuate fasciculus connects Wernicke's area in the left posterior STG with Broca's area in the left IFG. Recent studies have suggested a more extensive set of connections between language temporal and frontal areas. One recent view is that temporal–parietal areas incorporating AG, FG, and the temporal pole (TP) work with the pars orbitalis of the IFG to constitute a fronto-parieto-temporal network that is involved in semantic processing (Vigneau et al., 2006). The anatomical basis of this network includes the inferior longitudinal fasciculus that links posterior STS/angular sulcus (i.e., the portion of the STS that extends into the AG) to the TP and basal temporal language areas (Catani et al., 2002) and uncinate fasciculus connecting the TP and orbital frontal cortex (Catani et al., 2002; Horwitz et al., 1998; Nieuwenduys et al., 1988). This network is thought to play a role in semantics by constructing word meaning based on integrated knowledge from externally generated (e.g., vision and audition) and internally generated (e.g., emotion and long-term memory) information. A second network connecting the pars opercularis and the AG via the arcuate fasciculus is thought to be involved in working memory about word meaning. In this network, the AG may play a role in establishing semantic associations, whereas the pars opercularis might be more involved in semantic selection driven by task demands (Wagner et al., 2001).

Sentence Processing

Sentence comprehension requires integrating single word meanings into sentence-level meanings. Many linguists believe that this requires constructing sentence structures as an intermediary (Goldberg, 2006; Jackendoff, 2002; Pinker, 1999), although psycholinguistic data have provided substantial counterevidence against this modular perspective (Farmer et al., 2006; for a review, see Tanenhaus and Hare, 2007). Various tasks are used in fMRI studies of sentence understanding, such as passive listening or reading sentences (Crinion et al., 2003; Goel et al., 2000; Kansaku et al., 2000; Meyer et al., 2004), plausibility judgments of sentence meaning (Baumgaertner et al., 2002; Kuperberg et al., 2000; Zysset et al., 2002), emotional judgments (Kotz et al., 2003), mental imagery (Just et al., 2004), and generating sentences' final words (Kircher et al., 2001). Tasks probing syntactic processing include processing sentences with complex syntactic structures and detecting grammatical errors (Ben Shachar et al., 2004; Caplan, 2001; Constable et al., 2004; Cooke et al., 2002; Dapretto and Bookheimer, 1999; Embick et al., 2000; Luke et al., 2002). In this section, we will review

the brain regions involved in cognitive control and selection, processing structure and meaning, prosody and figurative language comprehension.

Cognitive Control and Selection during Sentence Comprehension

In the frontal lobe, the pars opercularis and pars triangularis of the IFG both seem to be involved in sentence comprehension. An area in the pars opercularis, located more caudally, is said to be involved in syntactic processing, such as comprehending complex sentences containing syntactic movement (Ben Shachar et al., 2004) and detecting grammatical errors (Embick et al., 2000). The pars triangularis is recruited during semantic processing related to grammatical processing, such as lexical categorization (Adams and Janata, 2002; Buchanan et al., 2000; Heim et al., 2002).

Although the frontal lobe is undoubtedly involved in sentence processing at some level, this remains somewhat in dispute. It is suggested that the functional organization of the frontal lobe might be determined by process type instead of stimulus type (e.g., verbal or nonverbal information) (e.g., Bornkessel-Schlesewsky and Schlesewsky, 2013; Wager and Smith, 2003). Numerous scholars have argued that Broca's region is involved in general processes of cognitive control rather than in linguistic computation per se (e.g., Stowe et al., 1998, 2005; Thompson-Schill et al., 1997, 2005). For instance, Novick et al. (2005) found an increase in left IFG activity for processing ambiguous sentences compared to unambiguous sentences. Their explanation was that sentences with ambiguity require selection among competing alternatives and that IFG helps coordinate this cognitive mechanism.

A meta-analysis of working-memory studies (Owen et al., 2005) indicated that the left IFG is recruited during selection, comparison, and judgment of stimuli. The authors suggest that the left ventrolateral IFG responds in a modality-independent manner to a variety of explicit task demands (e.g., explicit retrieval).

Processing of Structure and Meaning

In the temporal lobe, the middle MTG, posterior MTG, inferior STS, and posterior STG are activated during sentence processing.

The middle MTG is involved in comprehending sentences with simple or complex structures (Ben Shachar et al., 2004; Kansaku et al., 2000) and sentences that are syntactically or semantically incoherent (Luke et al., 2002). The posterior MTG appears to play a role in processing complex sentences (e.g., sentences that contain relative clauses) (Constable et al., 2004; Cooke et al., 2002). The middle MTG is also important in some semantic tasks (e.g., semantic association judgment) based on auditory and visual word presentation (Binder et al., 2000; Davis et al., 2004; Specht and Reul, 2003). The posterior MTG appears to be involved mainly in sentence *reading*, but it can also be activated by auditory presentation of sentences when subjects are asked to generate a mental image of the sentence content (Just et al., 2004). Current evidence suggests that MTG is an area that is of critical importance for using word meaning to understand sentences (Cooke et al., 2002; Dronkers et al., 2004; Vigneau et al., 2006), and it might also be important for cooperation between visual and auditory language processing networks during sentence processing.

The posterior STS is also sensitive to syntactic complexity (Constable et al., 2004), grammatical errors (Embick et al., 2000), syntactic generation (Kircher et al., 2001), and coherence in sentences (Kuperberg et al., 2000; Luke et al., 2002). One role of this area probably relates to the linkage of linguistic structure to meaning (Homae et al., 2002) and to the integration of linguistic material at the sentence level. The posterior STS also appears to play a role in the processing of theory of mind (TOM) (Gallagher et al., 2000) and inference development during narrative comprehension (Saxe and Kanwisher, 2003).

The inferior bank of the left STS is involved in sentence listening within meaningful discourse but not during unintelligible speech (Crinion et al., 2003; Kansaku et al., 2000; Meyer et al., 2004). It is also activated during syntactic plausibility judgment in sentence reading (Luke et al., 2002) and might be important for processing grammatical prosody (von Kriegstein et al., 2003).

The anterior temporal lobes are also active during sentence comprehension (Just et al., 2004; Kircher et al., 2001; Kuperberg et al., 2000; Luke et al., 2002; Stowe et al., 2005). Some researchers have claimed that the anterior temporal lobes play a critical role in the process of combining words into semantic chunks (Kintsch, 1998).

Figurative Language Comprehension

Figurative language refers to words and groups of words that exaggerate or alter the usual meanings of the component words. Figurative language may involve exaggerations and analogy to similar concepts or other contexts. The main fMRI studies on figurative language focus on metaphor, idiom, and irony comprehension.

Metaphor uses conceptual knowledge from a concrete semantic domain (e.g., a tangible thing or an image) to represent conceptual knowledge in an abstract semantic domain (Lakoff and Johnson, 1980). The figurative meaning of a metaphor can diverge from its literal meaning such that it is not obviously related to its original meaning. One important historical question, suggested by investigations of individuals with brain injuries (e.g., Monetta et al., 2006; Tompkins, 1990), is whether the right hemisphere plays a special role in comprehending metaphor. fMRI studies of metaphor processing give a mixed answer to this question, suggesting that right hemisphere involvement in metaphor comprehension can be influenced by several factors. One important factor relates to conventionality and novelty. In conventional metaphors, the figurative meaning is more salient and easy to access, whereas in novel metaphors, the literal meaning is more salient and the access of figurative meaning requires inference. According to the Graded Salience Hypothesis (Giora and Fein, 1999), the left hemisphere is more involved in processing conventional metaphors and the right hemisphere is more involved in the comprehension of novel metaphors. This view is supported by several fMRI studies. Lee and Dapretto (2006) showed that processing of conventional metaphors elicited stronger effects only in the left IFG, MTG, and IPL compared with literal comprehension, while Diaz et al. (2011) showed that comprehending novel metaphors evoked strong bilateral

effects, including activation in the right posterior MTG, TP, and IFG. Mashal et al. (2005) found that the right posterior MTG was involved in novel metaphor comprehension. Direct comparison showed that novel metaphors elicited stronger bilateral activations that included effects in the right frontal regions (Ahrens et al., 2007; Mashal et al., 2007) and the temporal regions (Mashal et al., 2007). Other differences have been found between novel and conventional metaphor comprehension. For example, Eviatar and Just (2006) revealed that conventional metaphors showed stronger activation than literal utterances not only in the left IFG and left ITG, but also in the right ITG. Several studies indicate that processing novel metaphors shows stronger effects only in the left brain regions compared with literal processing (e.g., Mashal et al., 2009; Rapp et al., 2004; Schibata et al., 2007). A recent meta-analysis using activation likelihood estimation found that the significant effects in the right hemisphere during metaphor processing occur when the metaphorical meaning is novel (Yang, 2012). This result supports the right hemisphere hypothesis on processing broad semantic fields and integrating distant concepts (Beeman, 2005).

Idioms are 'dead' metaphors (highly conventionalized metaphors), in which the figurative meaning is comprehended with regard to a common use of the expression. In idiom, the figurative meaning is directly (and holistically) retrieved from memory. fMRI studies of idiom comprehension have confirmed a bilateral brain network for processing idiomatic meaning. Zempleni et al. (2007) found processing of idiomatic sentences to involve IFG bilaterally and the left MTG. In Lauro et al. (2008), comprehension of idiomatic sentences elicited greater bilateral activations than comprehension of literal sentences. Effective connectivity analysis showed that the prefrontal cortex on both sides plays a crucial role in the selection between alternative sentence meanings. It is possible that the right hemisphere is involved in maintaining simultaneously various interpretations (Kacinik and Chiarello, 2007). In line with this, Mashal et al. (2008) found that compared to the idiomatic interpretation of idiomatic sentences, literal interpretation of idiomatic sentences elicited stronger activations in the right MTG, STG, and bilateral anterior insula lobe. The authors claimed that the right hemisphere is responsible for maintaining the nonsalient meaning (literal meaning), independent of figurativeness.

Irony is the use of words to express implied meaning other than and especially opposite to the literal meaning. Irony is widely used in daily conversation. Several fMRI studies have investigated the neural substrates of irony comprehension. Eviatar and Just (2006) found that listening to ironic statements results in stronger activation than to literal statements in the right STG and MTG. Wakusawa et al. (2007) investigated irony processing in real social situations. Participants were shown pictures depicting daily communicative situations and asked to judge situational appropriateness and literal correctness. The results showed the right TP to be involved in irony-specific processing, independent of task demand, while the medial orbitofrontal cortex plays a bigger role during irony comprehension only in the situational judgment task. The authors claimed that the right TP is involved in automatically assessing situational context during irony comprehension, whereas the medial orbitofrontal cortex is involved in judging the situational context. In Shibata et al. (2010), participants read a short scenario that consisted of five sentences. The first four sentences explained the situation of the protagonists. The fifth connoted an ironic, literal, or unconnected meaning. Then participants judged whether or not the final sentence expressed irony. Results indicated that both ironic and literal situations led to widespread bilateral brain activation, including the SFG, MFG, IFG, medial prefrontal cortex, STG, IPL, caudate, and thalamus, as well as the left insula and the left amygdala. Direct comparison between the ironic and the literal conditions showed higher activation for the ironic sentence in the right medial prefrontal cortex, the right precentral gyrus, and the left STG. Spotorno et al. (2013) found that verbal irony comprehension activated brain regions involved in the processing of TOM, including the bilateral temporal–parietal junction, the medial prefrontal cortex, and the precuneus. These results suggest that right fronto-temporal regions play important roles in irony comprehension, and that brain regions involved in emotion processing and processing of TOM contribute to understanding of irony.

In summary, sentence comprehension involves a brain network including the bilateral frontal and temporal regions for sentence processing. The temporal regions are important for comprehending sentences with complex meaning and syntactic structures, while the frontal regions are important for comprehension tasks that require cognitive control.

Discourse Processing

Discourse comprehension requires not only understanding of words and sentences, but also retrieval of world knowledge, semantic integration of current information with prior context, and coherence checking. An extended bilateral network is engaged during discourse comprehension as individuals make inferences and develop interpretations.

The tasks employed in the investigation of the neurobiology of discourse comprehension include reasoning (Caplan and Dapretto, 2001), topic judgment (Caplan and Dapretto, 2001), evaluation of connotation (Rapp et al., 2004), coherence judgment (Ferstl and von Cramon, 2001, 2002; Ferstl et al., 2005), attention to voice identity (Crinion et al., 2003), and moral judgment (Nichelli et al., 1995).

Previous studies have shown that auditory discourse comprehension activates a widespread bilateral fronto-temporal network, including the bilateral anterior temporal lobe, STG/STS, precentral gyrus, and pars triangularis and opercularis of IFG, MFG, and pre-SMA. Whether in a discourse context or not, speech perception per se is far more left lateralized, activating left MTG, posterior STS, left ITG/FG, pars triangularis of the left IFG, and the anterior temporal lobe bilaterally. Coherence checking during discourse comprehension activates the anterior temporal lobes bilaterally, the posterior STS bilaterally, as well as the middle MTG, pars opercularis, dorsal medial prefrontal cortex, and precentral gyrus, all on the left.

The bilateral middle and posterior MTG, STG, and STS are involved in semantic processing during discourse comprehension. The posterior portion of MTG might support a process providing initial access to meaning representations, such as

activating features and first-order associations of input words (Bookheimer, 2002; Demonet et al., 2005; Xu et al., 2005). The middle STG is activated during listening to permuted narratives compared with reversed narratives (Kansaku et al., 2000), making plausibility judgment of coherent sentences (Kuperberg et al., 2000), and comprehension of stories compared with listening to sentences of pseudowords (Ferstl and von Cramon, 2001). The middle STS plays a role in text comprehension (Kansaku et al., 2000), dialogue processing (Homae et al., 2003), and understanding coherent sentences (Kuperberg et al., 2000).

Compared to the middle and posterior temporal lobes, the anterior STG, STS, MTG, and TP (bilaterally) are multimodal association areas and appear to be responsible for integrating semantic, syntactic, and episodic information into a meaning representation of discourse content.

The pars opercularis and triangularis of the left IFG are involved in semantic selection that inhibits competing concepts while selecting one concept for action or for consciousness. The regions are co-activated with bilateral STG during word and sentence comprehension. In discourse comprehension, frontal areas appear to help process sentence-level context (Baumgärtner et al., 2002). The right pars opercularis and the anterior part of the right insula are involved in manipulation of information in working memory and decision-making. The involvement of these inferior frontal areas does not appear to be specific for one particular language component, but rather to be involved in cognitive control functions (Novick et al., 2005; Snyder et al., 2007). The right MFG is involved during auditory selective attention, independent of language stimuli (Jäncke and Shah, 2002; Poldrack et al., 1999; Sekiyama et al., 2003).

Finally, medial areas such as the orbital gyrus are involved during coherence checking. The orbital gyrus is activated in emotion processing in the context of verbal humor (Ferstl et al., 2005; Goel and Dolan, 2001, 2004; Siebörger et al., 2007) and in the integration of a current sentence with background knowledge in comprehension of funny cartoons (Maguire et al., 1999).

Additional Aspects of Language Processing in the Brain

Embodied Language Comprehension

The degree to which sensory–motor information is necessary for understanding the meanings of words and sentences has been the source of tremendous theoretical and experimental interest over the past decade.

Relevant theories can be placed on a continuum from not-at-all necessary ('unembodied') to crucial (strongly 'embodied'). Unembodied theories claim that sensory–motor information plays no causal role in semantic interpretation and there is an arbitrary relationship between the reference and the format of semantic information (Collins and Loftus, 1975; Landauer and Dumais, 1997; Levelt, 1989).

Some theories posit that although the format of semantic representation is amodal, it does not mean that there is a hard boundary between semantic information and sensory–motor information. These theories can be regarded as 'secondary embodiment,' which suggests that semantic representation is associated with sensory–motor systems but that sensory–motor representations are not causally involved in comprehension (Mahon and Caramazza, 2008; Patterson et al., 2007). According to these more integrated theories, activity in sensory and motor areas during semantic processing is secondarily affected by the connections mediating among semantic and sensory and motor information. Some adherents of this view propose the existence of a semantic 'hub' integrating information from sensory–motor locations (Rogers et al., 2004; Patterson et al., 2007).

A fourth view, of 'weak embodiment,' proposes that sensory–motor information partly contributes to semantic representation and is not just accessed secondary to abstract semantic information (Simmons and Barsalou, 2003; Vigliocco et al., 2004). In this view, semantic information relies on association areas that integrate modal information, but this information is distinct from raw experience processed by primary sensory–motor cortices.

Views that embrace strong embodiment claim that low-level sensory and motor information is activated in primary cortical areas and this activation is in service of semantic processing. They have generally shown the former but not established the latter. Sensory–motor systems are used to represent semantic information and can be modulated by semantic processing (Glenberg and Robertson, 2000; Zwaan, 2004). For example, Pulvermüller (1999) proposed that brain regions involved in processing of word-form and semantic related sensory–motor information 'wire together' during word meaning acquisition, and thus these areas 'fire together' during word comprehension. Gallese and Lakoff (2005) proposed that the same neural substrates are used for perceiving/doing, imaging, and language comprehension.

Thus far the neuroimaging evidence supports a degree of embodiment. Several findings indicate that semantic processing activates brain areas anterior to the primary sensory–motor areas involved in direct experience (Chatterjee, 2008, 2010; Martin et al., 2000; Thompson-Schill, 2003; Wallentin et al., 2005; Willems et al., 2010a,b). For example, Bar et al. (2001) showed that when participants viewed pictures about objects, areas in the ventral stream become active. The areas are anterior to those involved in visual shape perception. Wallentin et al. (2005) found that sentences describing actual and fictive motions activate brain areas anterior to MT/V5. Willems et al. (2010a,b) showed that comprehending action language elicits activity in the premotor cortex instead of the primary motor cortex. Tremblay and Small (2011b) found that different parts of the ventral premotor cortex were involved during action observation and action sentence comprehension. In another study, Tremblay and Small (2011a) found that the left ventral premotor cortex was significantly active during speech perception and production, but that activation was scaled to articulatory complexity only during speech production. This suggests an incompletely specified efferent motor signal during speech perception. Taken together, these findings indicate that sensory–motor information may be abstracted from direct experience and question the necessity of simulation during semantic processing. Complex conjunctions across modalities can represent more schematic and abstract information (Chatterjee, 2010).

Some recent studies have suggested that individual differences can shape the sensory–motor activations during language comprehension. Beilock et al. (2008) and Lyons et al. (2009) found that experienced ice-hockey players have stronger activations than nonhockey players in the left premotor cortex when they process sentences about hockey actions, but not when they process sentences about daily actions. Willems et al. (2010) indicated that handedness can influence motor activity during comprehension of hand verbs. Right-handed participants showed activity in the left premotor cortex during action verb comprehension, while left-handed participants indicated activity in the right premotor cortex. These results suggest that language comprehension is an embodied process and there is variability between individuals.

Nonverbal Information in Language Comprehension

During language comprehension, nonverbal information, such as facial expressions, gestures, and body movements, plays an important role. Recent fMRI studies provide evidence for the nonverbal information processing.

One important type of nonverbal information is gestures (for reviews, see Andric and Small, 2012; Goldin-Meadow and Alibali, in press). Studies about co-speech gestures (Dick et al., 2009; Green et al., 2009; Holle et al., 2008, 2010; Hubbard et al., 2009; Kircher et al., 2009; Skipper et al., 2009) and emblems (e.g., Lotze et al., 2006; Montgomery et al., 2007; Nakamura et al., 2004) have shown that IPL, SMG, and intraparietal sulcus (IPS) are strongly involved, though the laterality of SMG and IPS are not consistent across studies (Green et al., 2009; Lotze et al., 2006; Willems et al., 2007). In the frontal lobe, the bilateral premotor cortex is activated when viewing emblems (Nakamura et al., 2004; Montgomery et al., 2007; Villarreal et al., 2008) and co-speech gestures (Kircher et al., 2009). Distinct roles appear to exist for the ventral and dorsal premotor cortex. For example, Kircher et al. (2009) indicated that the ventral premotor cortex becomes active when people view metaphoric gestures, while Hubbard et al. (2009) found that the bilateral dorsal premotor cortex is activated when viewing beat gestures. The ventral premotor cortex might be sensitive to the semantic contribution of gesture (Skipper et al., 2007; Willems et al., 2007). Taken together, the premotor and parietal areas are involved in general gesture processing.

The IFG and lateral temporal cortex are involved in processing emblems that communicate meanings independent of speech (Goldin-Meadow, 1999; Gunter and Bach, 2004). The pars triangularis of IFG is thought to be important for interpreting gesture meaning as it does in interpreting language meaning (Kircher et al., 2009; Willems et al., 2007). The pars opercularis is also activated during gesture processing, particularly during co-speech gesture (Dick et al., 2009; Green et al., 2009; Kircher et al., 2009) and mouth and hand actions (Binkofski and Buccino, 2004; Rizzolatti and Craighero, 2004). In the temporal lobe, lateral temporal areas also respond to speech accompanied by gestures. The posterior STS responds to co-speech gestures and might play a role in integrating iconic gestures and speech (Holle et al., 2010). The bilateral posterior MTG is activated when people see metaphoric or iconic gestures (Green et al., 2009; Kircher et al., 2009; Willems et al., 2009). The anterior STG is activated in co-speech gesture processing (Skipper et al., 2007, 2009; Green et al., 2009; Straube et al., 2011) and emblem processing (Lotze et al., 2006) and might be involved in context processing. In a word, the IFG and lateral temporal cortices might respond to meanings independent of modality (Andric et al., in press). This suggests that interpretations of speech and gesture share a common neural substrate.

In addition to the investigation gesture processing during speech comprehension, researchers have also found that visual processing of mouth movements profoundly influences human speech perception. For example, watching a speaker's mouth movements improves speech comprehension, especially for normal listeners in noisy environments and for the hearing impaired (Grant et al., 1998; Sekiyama et al., 2003; Sumby and Pollack, 1954). Several brain regions have been found to be involved in cross-modal integration during speech perception, including STS, IPS, IFG, insular lobe, and Heschl's gyrus (Calvert et al., 1999, 2000, 2001; Callan et al., 2003, 2004; Olson et al., 2002; Beauchamp et al., 2004; Mottonen et al., 2004; Pekkola et al., 2005). These findings indicate that merging information from different modalities enables faster and more accurate discrimination than unimodal stimuli.

Conclusion and Further Research Directions

From the above review, two general conclusions can be seen in the current fMRI studies about language comprehension.

The first is that single language components (e.g., phonological processing) cannot be isolated functionally or anatomically. No function is localized in one particular brain region, but instead, each component is supported by a network that contains several regions and dynamic interactions among the regions. Connectivity analysis methods, such as functional connectivity and effective connectivity analysis, are used to examine the correlations or influences between regions. In addition, methods such as diffusion tensor imaging are used to detect structure connectivity. Further work using techniques such as quantitative meta-analysis should help elaborate connectivity patterns across brain regions (Cauda et al., 2011; Robinson et al., 2009).

The second is that understanding words and sentences, whether literal or figurative, requires representing and/or making use of semantic information, and how this information is encoded in the human brain remains a critical area for research. The notion that sensory–motor information plays a role in these processes is not much in dispute, but the nature and degree of this role is not known. On the one hand, sensory–motor information related to semantic content of the language stimuli is involved in language comprehension. The involvement of sensory–motor regions has been found to be flexible and context dependent. Yet the exact contribution of the sensory–motor system in comprehension, particularly related to its causal role in comprehension, still remains unclear. Furthermore, nonverbal information plays an important role. For example, visual perception of actions such as mouth movements and gestures can influence language

comprehension, and brain networks involved in understanding these actions are not distinct from those involved in understanding words and sentences. Future research will focus on the contextual influence on the integration of language and gesture processing.

Abstract

Trained in the grand Analysis of Euler, d'Alembert, and Lagrange, Laplace found himself at a scientific crossroads which was unique in the modern history of science. In fact, in the last quarter of the eighteenth century, Laplace was to solve in succession a large number of the problems left unresolved by Newtonian theory. Celestial mechanics, which had seemed limited to the description of general phenomena, was able to explain the system of the world down to its finest details and with unlimited precision; scientific determinism was thus possible and Laplace's *Celestial Mechanics* was a decisive proof of this. This constantly enhanced precision could reach to a fine degree the then inaccessible areas of the moral sciences. The second Laplacian message, the *Analytical Theory of Probability*, allowed the scholar to assess data from the whole of nature, and in the long term reveal the 'constant causes' which affect and determine human society. It could also, in the absence of a large number of observations, guide man in his choices by eliminating arbitrariness and error as far as possible. Laplace's considerable scientific work, spanning the years from 1770 to 1827, was to consist in constantly asserting that mathematical analysis could allow Mankind to become master of its universe with an unparalleled precision and efficacy.

Pierre-Simon de Laplace was born on 23 March 1749 in Beaumont-en-Auge into a well-to-do family of the Norman landed gentry which occasionally married into the nobility. Destined for the priesthood, he studied first at the College de Beaumont under the direction of the Benedictines of Saint-Maur. Endowed with an excellent memory and a keen intellect, Laplace seems to have excelled at the College, where he received the classical education of the time – the great Latin and French authors, in particular Virgil, Cicero, and Racine, whom he liked to cite and who are perhaps the origin of his obvious liking for well-turned phrases and his passion for physical astronomy. At the age of 16, he entered the College of Arts at the University of Caen for the 2 years of philosophy prior to the Degree in Theology. Here he discovered mathematical analysis in his dealings with natural philosophy, Euler, Clairaut, d' Alembert, and Daniel Bernoulli, and at the same time discovered his astonishing aptitude for handling formulae. On the advice of his tutors, he abandoned theology and moved to Paris in 1769, where he was very quickly noticed by d' Alembert. From then on, he was never to leave either Paris or analysis.

Programme of Studies

As Professor of Mathematics at the Ecole Royale Militaire, Laplace was literally to inundate the Académie des Sciences with mathematical papers, some 15 in 4 years, certain ones of which ran to well over one 100 pages in quarto. On 24 April 1773, he was elected *adjoint mécanicien* at the Académie des Sciences in Paris. The subjects which he tackled were those which he would continue to explore for the whole of his scientific life, a life which was to prove exceptionally long, especially as he would continue publishing original and fundamental papers right up to his death in Paris on 5 March 1827.

Becoming very quickly aware of his intellectual superiority, Laplace set about tackling all the problems of his day in the three principal academies where exact sciences were fostered – Paris, Berlin, and St Petersburg. Indeed, one need only read the titles of his first papers to get a good idea of the state of mathematical sciences in the last quarter of the eighteenth century. First and foremost came differential and integral calculus, and in particular the study of differential equations and partial differential equations which governed the mechanics of solids as well as fluids and the stars. In a paper presented in 1773 (Laplace, 1912, vol. 9, pp. 5–68), it was Laplace who was the first to demonstrate that in very general cases one could determine the whole integral of linear partial differential equations, and that in exceptional cases it was still possible to obtain from them particular solutions in the form of *defined integrals* that is, *integral transforms* which fitted with the initial data. This method would allow him, for example, in 1809, to solve the equation of heat in more general cases than those envisaged by Fourier.

The second subject tackled by Laplace equally concerns the solutions of differential systems, but in those cases where whole integrability is beyond reach, such as in the theory of the Moon or the large planets. These theories had not only eluded Newton, who had not used the infinitesimal algorithm in its full extension, but had also eluded Euler, Clairaut, d' Alembert, and Lagrange who were ingenious rivals in their use of it. Laplace, right from the outset, was to demonstrate his extraordinary faculty – often spoken of in terms of intuition – for reducing by approximation the irreducible difficulties present in equations dealing with the problems of multiple bodies. In March 1773, Laplace presented a paper (Laplace, 1912, vol. 8, pp. 201–275) on the 'principle of universal gravitation' in which he showed that Euler and Lagrange had been wrong in their planetary theory and that he, Laplace, at the age of twenty-four, through Newton's single principle that 'the planets gravitate against each other,' could show the absence of secular inequalities in planetary mean motions, so that the planets could not accelerate their motion around the sun irreversibly by themselves. Furthermore, they only deviated from their perfectly elliptical trajectories through periodic and temporary inequalities, thus assuring a stability in the 'system of the world' which Laplace would encounter again in all areas of his work. The mechanics of the planets is quasi-stable, and

the God of Newton played no useful role in maintaining them within rational limits. The foundations for Laplace's astronomical work were established, a work which he never once doubted and which he would pursue from then on, right up to his death.

The third subject, the 'theory of chance,' is more surprising coming from a protégé of d'Alembert, but it was of great topical interest in 1770. It was in fact in this year that the great academies suddenly resumed this subject, which had to some extent been abandoned for 50 years, and which was now brought back into fashion by works in political arithmetic – notably those of Süssmilch – and at the same time by the requirements of astronomy. Lambert, Euler, Daniel Bernoulli, Lagrange, and Condorcet simultaneously published important papers on *probability calculus*. It was therefore inevitable that the young Laplace would turn his efforts to it, and his first contributions were magnificent, notably the great paper 'on the probability of causes' published in 1774 (Laplace, 1912, vol. 8 pp. 27–65), which marked the beginning of Laplacian mathematical statistics. In this paper, one of the classic works of the theory, Laplace developed the analytical results of the proportionality principle from the probability of causes to that of effects, and, for the first time, proposed, as a criterion for estimation, a quantity known only from observations subject to unavoidable errors, this criterion serving to minimize the sum of potential errors through their respective probability. This method, which Laplace called the *method of situation* and which appeared to him to be the result of the nature of things, should, he believed, be applied to research in astronomical fields. In fact, it led to formidable mathematical difficulties which Laplace would, in the next 50 years, work on breaking down into a series of fundamental works which would culminate in 1812 in the publication of the *Analytical Theory of Probability* (Laplace, 1820).

Analysis, *celestial mechanics*, and the *theory of probability* were three overlapping subjects which Laplace did not invent and which he already found in the academic papers of his time, but which he grappled with and never abandoned, to such an extent that he was to change the view scholars had formed of the world which surrounded them, a physical world, of course, but also a moral world from the moment when it could be converted into numbers.

Celestial Mechanics

The years which were to follow were a long succession of scientific triumphs. One after another, Laplace solved the most difficult problems in celestial mechanics posed since Newton, problems which had foiled the attempts of the most eminent scholars of the eighteenth century to such an extent that it was sometimes doubted whether the single principle of attraction could really account for the inequalities of motion – such as the secular inequality of the Moon, the inequalities of Jupiter and Saturn, the theory of the satellites of Jupiter, and so on – which were being brought to light by the increasingly precise observations of modern astronomy. Laplace's works as a whole – which were spread over 20 years – were brought together in a vast treatise, *Celestial Mechanics* (Laplace, 1825), the publication of which began in 1799, and which Laplace would continue to expand and amend up to the end of his life. Concurrently, in 1796 he published *Exposition of the System of the World* (Laplace, 1984), which was aimed at a wider readership and presented, in layman's terms, the principal results which demonstrated with the utmost clarity that Newton's law of universal gravity 'represents all celestial phenomena, right down to their smallest details' and that 'through this, empiricism has been entirely removed from Astronomy, which is now a major problem of mechanics.'

However, Laplace was well aware of the fact that whole areas of the system of the world existed where empiricism seemed difficult to exclude entirely, such as the theory of oceanic or atmospheric tides; in other words, the areas where 'irregular causes' occurred in an anarchic fashion which could, if one did not bear them in mind, conceal the true causes of phenomena and their fixed order. Laplace encountered this problem from the beginning of the 1770s to the moment when the theory of errors began to take shape. Observations of all parts of nature, even the most precise, were affected by 'unavoidable errors' which could prove themselves predominant if left to accumulate by chance, and remove all scientific value from the apparent objectivity. According to Laplace, it was therefore necessary to multiply the observations, adjust the value of the uncertain elements progressively, and reveal gradually the phenomena which were 'until this point shrouded in the errors of observations.' This progressive revealing could not be done without a method, and this is precisely the purpose of Laplace's probability calculus.

The Analytical Theory of Probability

For Laplace, probability theory was first conceived as a means of critically analysing data from observation, a critical analysis which gradually became more refined and revealed the true system of the world. Two periods in Laplace's development are usually distinguished. The first, which runs from 1774 to 1785, saw the development of Laplace's first method. In the spirit of Bayes, but essentially asymptotic in that it was independent of the special nature of *a priori* laws, it did not allow Laplace to deal with the major problem of the theory of errors, that is, to determine in the best possible way the elements known from a large number of indirect observations. It did, however, allow him to solve the population theory problems posed by Daniel Bernoulli and Condorcet by giving political arithmetic the scientific rigor it lacked, left open as it was to the most trivial empirical digressions; for example, in deciding whether in truth more boys were born in London than in Paris for the same number of births, or even whether the population of France was increasing or decreasing.

The second Laplacian asymptotic theory, this time non-Bayesian, began in 1810 after its author had solved one of the major problems of probability theory, the *central limit problem* as it is called today, where under very general conditions the total sum of errors is asymptotically normal, which allows the calculation of probability even if the particular law of errors is unknown. This remarkable theorem and its applications in the *method of least squares*, published the following year, makes up Chapter IV of Book II of the *Analytical Theory of Probability*, published by Laplace in 1812 (Laplace, 1820), and

bringing together his work on probability as a whole. This second great treatise from Laplace would be expanded with various different chapters until 1825. From 1816, Laplace gradually extended the applications of probability calculus into increasingly wider fields, anticipating a large number of the applications which the twentieth century would develop. The theory of probability, therefore, became for Laplace 'the most felicitous addition to the ignorance and weakness of the human spirit' as he asserts in conclusion to his *Philosophical Essay on Probability* (Laplace, 1986), the first edition of which dates back to 1814 and the last to 1825.

Laplace did not limit the possibilities for the application of probability calculus to traditional fields such as games, the theory of errors, and annuities. From the moment when a shred of calculation seemed to him possible, whatever the field and however tenuous it may be, he got to grips with it and generally exceeded previous results by a great deal. For example, inspired by the works of Daniel Bernoulli, Laplace moved from population theory to a general reflection on the chance series of draws from a ballot box which, at first, only display disorder and chaos and gradually adjust and give way to the simplest and most admirable order, the irregular causes cancelling each other out to display the eternal action of constant causes. These reflections on order in chaos anticipate the work on statistical physics at the beginning of the twentieth century. What is more, Laplace, inspired by Condorcet, proposed a theory of decisions in majority voting where the basic concepts of modern test theory can be seen. Further still, inspired once again by Daniel Bernoulli, Laplace established a general result for the concave utility functions, and applied it to questions of maritime insurance and so on. One can also see many more things in the *Analytical Theory* (Laplace, 1820), which make this work a monument of science for all time. (See Bibliography for complete studies on this subject.)

Career

After the flamboyant beginnings we have seen, Laplace was very quickly recognized by his peers, and if his arrogance had caused him some trouble at the beginning, he had an exceptional career. Elected in 1783 to the position of Associate Academician, he became a member of the Académie des Sciences in Paris in 1785. During the French Revolution, Laplace retired to a property near Paris to draft out *Celestial Mechanics* and kept himself at a distance from events. But with the fall of Robespierre, he returned to Paris and took an active part in the creation of three great scholarly institutions emerging out of the Revolution – the Institut de France, the Bureau de Longitudes, and the Ecole Polytechnique. Bonaparte, who was concerned about his image and the scientific glory of France, was to make Laplace, albeit short-lived, his First Minister of the Interior and soon one of the highest dignitaries of the Empire, the Chancellor of the Senate, and Count of the Empire.

In 1814 Laplace voted with the majority of the Senate for the forfeiture of the Emperor. He was immediately made a peer of France, then marquis, by King Louis XVIII. In the numerous positions he held, Laplace made himself the herald and the defender of exact sciences. He involved himself little in politics, and when he did, only with questions he could reduce to numbers.

In his lifetime, Laplace enjoyed an immense scientific prestige. As founder of the Société d' Arcueil in 1807, he addressed all the scientific debates of his time, and created a brilliant school which would make his mark on part of his century, up to the point at which Laplacian physics of corpuscular fluids was superseded by positive mathematical physics and experimental physics (on this subject, see Gillispie, 1997).

In 1788, Laplace married Charlotte de Courty (1769–1862) with whom he had two children, Charles (1789–1874), general and peer of France who died without descendants, and Sophie (1792–1813) who died in childbirth. Angelique (1813–89), the only daughter of Sophie, was brought up by her grandparents and married the marquis de Colbert Chabanais and had three children, through whom the family line was established.

Influence

Laplace was one of the most influential men of science of all time, as much through his scientific work as through his two expository works which met with considerable success. There was no public or private library which did not possess them, and Laplace remains among the most cited scholars in present-day literature. His contribution to the formal assertion of mechanical determinism is sometimes summarized thus: 'All events, even those which by their insignificance do not seem to be due to the great laws of nature, are a consequence of them which is as necessary as the revolutions of the sun.' This introductory sentence from the *Philosophical Essay* (Laplace, 1986) of 1814 which can already be found in one of Laplace's first philosophical texts written in 1773 is without doubt the most frequently occurring scholarly quotations in the whole of world literature. In fact, as is well known, the assertion of determinism is a recurrent theme in the history of human thought, and countless authors in the eighteenth century in particular could be credited with it. Laplace's originality lies in producing a brilliant proof; that the tiniest disturbances in the system of the world – for example, the slow acceleration of the Moon – are a necessary consequence of the single best established law of nature, that of universal gravity. It was because such a deduction was possible, as Laplace demonstrated, that determinism could be asserted and, even more, that it was then a question of one of the highest scholarly ambitions of humanity. Science in the nineteenth century became a race for precision made possible by the local determinism of phenomena in the whole of nature.

However, Laplace's influence extends well beyond that particularly in the social and moral sciences of the nineteenth century, most notably in the work of Quetelet. Indeed, 'Laplacian determinism' was not limited to determinist phenomena. In the system of the world, there are numerous phenomena which are subject to irregular accidental causes which constantly alter the course of these phenomena. Necessity, order, and determinism are nevertheless not absent from them. For example – and it is an example dear to Pastor Süssmilch which Daniel Bernoulli took up again – the sex at

birth does not seem to be subject to any determinism, yet one observes that always or almost always slightly more boys are born than girls as soon as one considers quite a large number of births. Laplace concludes that the invariability involved here is 'a result of regular causes which override the anomalies due to the chance' of irregular causes (Laplace, 1912, vol. 7, p. xlviii). Chance is thus furnished with a special meaning; it is the combination of irregular causes which take effect in all directions, without favoring any one in particular. Regular causes, on the other hand, compel nature along enforced paths which become apparent in the long term. This is Laplace's *theory of constant causes* which one can clearly see in the works of other authors, for example Buffon, Moivre, and the Bernoullis, but also in the works of the ancient Stoics. It is Laplace, however, who, just as in the case of determinism in minor astronomical perturbations, provides this theory with a mathematical provision which justifies its implementation. This is the full import of his theorem of 1810; the variations due to *irregular causes* are enclosed in narrow limits determined by the Laplace formula, which gradually move closer to genuine elements in such a way that the constant causes determine them. The analysis of causes which Adolphe Quetelet undertook of the 'phenomena which organised beings present us with' is no different, except in that it integrates into the Laplacian constant causes–accidental causes schema a third type of causes, *variable causes* which, for example, produce seasonal effects, causes which Poisson, Cournot, and Bienaymé had envisaged in order to account for irregularly periodic statistical data. Quetelet's 'average man,' and the 'tendencies to crime,' can only be understood in the perspective of the constant causes in Laplace's *Essay*. In a still more obvious way, Poisson's 'law of large numbers' is a triumphant metaphor for Laplacian theory, or at least for certain aspects of it – showing as it does the order of constant causes within the apparent chaos of accidental causes.

The decision-making aspect of Laplace's work – the theory of probability seen as 'common sense reduced to calculation' – experienced a less glorious fate. After the Laplace school – Poisson, Cournot, and Bienayme – had attempted to give it a more acceptable form in the first half of the nineteenth century, it was for a long time rejected, and with this rejection went an increasingly significant part of Laplace's work on probability. Causes were multiple and, moreover, 'variable' since this aspect a century later was reinstated at the highest level in the way that it is best known today – the theory of games, the theory of decisions, the theory of tests, and judgments based on samples. For Laplace, chance was also the name for our ignorance, an ignorance which was often incurable owing to those multiple accidental causes which distort the natural order of things and of our reason, so that the eminent role of the theory of chance, of probability calculus, is to 'criticize' the statistical data from all parts of nature; and even in the absence of data, by analogy, image, model, and calculation when possible, the theory still allowed one to find one's way more confidently through the maze of social and economic life. In France one would have to wait for Borel and his theory of games before one considered afresh along with Laplace that the theory of probability 'leaves nothing arbitrary in the choice of opinions and in the choice of decisions to make, every time one can determine, in one's way, the most advantageous choice.' Laplace's legacy – to perfect everything through the powerful means that mathematical analysis places at the scholar's disposal – is in no danger of being forgotten.

Abstract

Large-scale social surveys are an important source of information for a wide range of topics. Analysis of such surveys can be challenging. Given the difficulties of constructing a sampling frame, implementing probability sampling, and obtaining a high response rate, it is no surprise that analysts must often make major efforts to adjust for differences between sample and population, using tools including weighting, imputation, regression modeling, and poststratification.

Quick Recommendations

Large-scale social surveys are an important source of information for a wide range of topics. In analyzing such surveys, it is important to be aware of the complexity of the sampling design and the data adjustments that are used by survey organizations, including weighting to adjust for differences between sample and population and imputation to fill in missing responses. For estimating population means and proportions, the analyst should calculate weighted averages, using survey weights. In regression analysis, it is best to include, among the predictors, the variables that are used in the design and the weighting. Hierarchical models can be used to obtain inferences for small subpopulations, and poststratification can be used to aggregate cell-level estimates to obtain inferences for larger segments of the population. In general, analyzing survey data as if they had been obtained through simple random sampling can result in biased point estimates and underestimated standard errors. These calculations can often be adjusted reasonably well by using design effects reported in the survey documentation or in previous analyses. For more involved analysis, it is advisable to use statistical packages that are specifically designed to correctly handle complex survey data, and to explicitly adjust for variables with mismatch between sample and population rather than simply relying on unit-level weights.

Background

Large-scale social surveys provide an inexpensive and easily accessible source of information on a wide range of topics including education, health, economics, demography, politics, and criminal justice. These surveys may serve as a primary data source, a preliminary data source to be analyzed prior to conducting a more tailored survey, or in combination with smaller, more specific data sources. After summarizing the advantages of using large-scale social surveys, the authors discuss how to confront the challenges they present.

There are many advantages to analyzing data from large-scale social surveys. The data are usually extensive in content and coverage of the target population. Sample sizes are often very large and the data are often easily obtained from the sponsoring agency on CD-ROM or from the Internet, in many cases at no cost to the researcher. Moreover, these surveys are typically conducted by large government agencies or private survey organizations that have experienced interviewers, well-designed and tested survey instruments, and the expertise to design efficient sampling plans. As a result, the response rates are typically high (e.g., 75–90%) and sophisticated nonresponse adjustments are often incorporated into the data to try to reduce nonresponse bias that results from systematic differences between respondents and nonrespondents. The sample data are also often reweighted, using poststratification, to agree with known population distributions of characteristics such as age, sex, and race. Finally, many surveys contain panel (longitudinal) components in which the same sample units are interviewed repeatedly over time, allowing researchers to follow individual changes over time.

The analysis of large-scale social survey data also presents several difficulties. One of the greatest technical challenges arises because sampling in these surveys is usually carried out according to complex multistage designs that combine stratification, cluster sampling, and unequal probability sampling. Many surveys that are repeated on a regular basis also rotate respondents in and out of the sample. Often, point estimates of simple estimands such as population means and proportions can be calculated using a minimal amount of information about the sampling design, but standard error calculations must incorporate the key sampling design elements explicitly. Survey weights, provided along with the survey data, contain important sampling design information. Correct interpretation and use of these weights is key to the analysis of large-scale social survey data, and particularly key to standard error estimation. Analysts must also be aware of the impact of nonresponse adjustments – such as weighting class adjustments for unit nonresponse and imputation for item nonresponse – on standard error estimates. Complex multistage sampling must also be taken into consideration when calculating confidence intervals for population parameters. In particular, the degrees of freedom used when calculating confidence intervals using a t-distribution depend on the sampling design, not solely on the sample size. Methods of incorporating survey weights into estimates of simple population parameters such as means, totals, and proportions are well established; however, the appropriate approach is less obvious when fitting more complex statistical models such as linear regression models and loglinear models. The authors address each of these issues in the following sections.

Complex Sample Designs

Although simple random samples are the easiest to design and analyze, large-scale social surveys often take advantage of complex multistage sampling designs to increase the precision of the resulting estimates. These designs typically involve multiple stages of sampling. For example, the first stage of sampling may select a sample of counties; the second stage may select a sample of subregions within each sampled county; the third stage may select a certain number of sample units (e.g., individuals, households, or hospitals) within each sampled subregion. Units selected at the first stage of sampling are called primary sampling units (PSUs). Units selected at the final stage are called ultimate sampling units. One reason for multistage sampling is to minimize the travel costs of interviewers in face-to-face surveys. Another reason is that a sampling frame (a list of all the ultimate sampling units in the population) may not exist for the target population, but may be constructed sequentially as needed. For example, a list of all school-age children in a state may not be readily available, but a list of all school districts in a state may be available; then for a sample of school districts, a list of all the schools in those districts may be obtained; then for a sample of schools, a list of children may be obtained.

Multistage designs often involve cluster sampling in which groups of sampling units are selected, rather than individual units. Examples of cluster sampling include selecting several students in a class, several households in a city block, or several patients in a hospital. Cluster sampling tends to increase the variability of survey estimates compared with a simple random sample of the same size. This occurs because units in the same cluster tend to be correlated and, as a result, each additional unit sampled within the same cluster provides less additional information about the overall population parameters than an element selected at random from the population. However, due to travel costs, frame construction costs, and other overhead costs associated with each sampled cluster, a simple random sample may be much more expensive than a cluster sample of the same size. Therefore, given a fixed budget, a cluster sample may provide the most efficient estimates.

Another common design element used in large-scale multistage surveys is stratification, which involves dividing the population into nonoverlapping segments, called strata, and sampling independently within each stratum. Typical stratifying factors include region of the country and urbanicity (urban, suburban, and rural). If the variable of interest tends to take on different values, on average, in each stratum, then stratified sampling can lead to more efficient estimates. In particular, the sample can be optimally allocated so that a larger sample is obtained in strata where there is larger variability in the variable of interest. Another reason for stratification is to ensure adequate representation of all segments of the population, avoiding the possibility of a simple random sample that, by chance, omits part of the population. Often certain strata, such as those containing a large proportion of racial minorities or elderly people, are sampled at a disproportionately greater rate (oversampled) in order to ensure an adequate sample size for research hypotheses that involve these groups. For example, the British Crime Survey oversamples inner city areas by a factor of two (Mirrlees-Black et al., 1998). Sometimes a census is conducted in some strata, called self-representing or take-all strata. This type of stratification is particularly useful for very skewed populations that contain a few large units and many small units (e.g., Hidiroglou, 1986). Stratification can also be combined with cluster sampling. For example, neighborhoods may be stratified by geographic region and then a sample of households within neighborhoods may be selected; or schools may be stratified by size and then a sample of classes may be selected from each school.

Unequal probability sampling is often used when sampling clusters. In particular, clusters are usually selected with probabilities proportional to their size (PPS) sampling, with larger clusters having greater probabilities of selection. The size measure used will depend on the survey, but, as examples, a school can be measured in terms of the number of students enrolled, a company can be measured in terms of the numbers of employees, a farm can be measured in terms of acreage, and a city block can be measured in terms of the number of households. PPS sampling will lead to more efficient estimates whenever cluster totals are proportional to the size of the cluster, which is often the case. For example, larger schools tend to have more students with learning disabilities, larger companies tend to have larger revenue, larger farms tend to have a larger crop yield, larger city blocks tend to have more single parents. Unequal probability sampling is also sometimes used for convenience. For example, random-digit-dial telephone surveys actually select households with probabilities proportional to the number of voice telephone lines in the household. Selecting a simple random sample of households would require a list of the individual households, rather than a list of telephone numbers, and this may be much more difficult to obtain or construct than a list of telephone numbers.

Finally, many large surveys that are repeated on an ongoing basis (e.g., monthly) use rotation groups. Rather than select new nonoverlapping samples each month, rotation groups remain in the sample for several months in a row (Fienberg and Tanur, 1983; Iachan and Jones, 1987). Every month, a new rotation group enters the survey and an old one drops out so that each month only a fraction of the sample units are new. This reduces costs by not having to draw a new sample each month (there are administrative costs with drawing a new sample, locating the new sample members, explaining the survey to them, etc.) and also provides some longitudinal information. Rotation groups present no complication to cross-sectional analysis of a single wave of data but can complicate analyses that combine several months of data since the same sample units may appear multiple times in these combined datasets. Analysis should then account for correlations between repeated measurements on some sample units. In contrast, some surveys, called rolling surveys (Kish, 1998), are specifically designed with nonoverlapping samples each month so that the resulting data can be analyzed for a single month or combined over several months to form larger datasets.

Survey Weights

The simplest analysis of survey data assumes that all elements in the population are equally likely to be included in the sample. Unfortunately, this is not generally true for two

reasons. First, complex sampling designs often lead to unequal selection probabilities, as discussed in the previous section. Second, even if units are equally likely to be selected, they generally have different probabilities of response; for example, in household surveys, women are usually easier to reach and more likely to cooperate than men.

Survey weights are used for correcting for known or expected differences between sample and population; each unit i is given a weight, w_i, and the population mean of any variable y is estimated by the weighted sample average, $Sum_i\ w_i y_i / Sum_i w_i$.

As the formula indicates, only the relative values of the weights are relevant. The weights are usually calculated by the survey producers and provided along with the survey data. An informal interpretation of these weights is that w_i is proportional to the number of units in the population represented by respondent i. Estimates of population proportions are calculated using the same formula, where y_i is a variable taking on values of 0 and 1.

Survey weights in large-scale surveys are often constructed so that sample estimates agree with current census estimates of key variables such as age, sex, and race, through a process called poststratification and raking (Oh and Scheuren, 1983; Gelman and Carlin, 2001). Voss et al. (1995) detail the various design and weighting strategies used by various national polling organizations for preelection surveys. Survey weights are also often adjusted to account for nonresponse, through a process called weighting class adjustment (Oh and Scheuren, 1983; Kalton and Kasprzyk, 1986; Bethlehem, 2001).

In most complex multistage samples, sampled units have different survey weights. However, it is possible to design these samples so that all sampled units have the same weight. These designs are called self-weighting (Cochran, 1977: p. 91) because the usual unweighted estimators, the same ones used for simple random samples, will produce unbiased estimates of population parameters such as means and proportions. However, the usual unweighted standard error estimation formulas are not necessarily appropriate in these designs. Therefore, although self-weighting designs may simplify point estimation calculations, they do not simplify standard error estimation calculations.

Finally, many surveys produce separate sets of weights for different types of analyses. For example, the US General Social Survey (GSS) (Davis and Smith, 1992) provides separate weights for household-level estimates and for individual-level estimates. The GSS is designed to give each household an equal probability of inclusion in the sample so that the sample is self-weighting for household-level variables. However, since only one individual in each household is interviewed, people living in large households are less likely to be interviewed than people in smaller households. Therefore, even though each household has an equal chance of being selected, individuals have different chances of being selected depending on the size of their households, with these inclusion probabilities varying by the type of survey (Gelman and Little, 1998). Longitudinal studies may also have separate cross-sectional and longitudinal weights. For example, the 1993 US Panel Study on Income Dynamics (PSID) provides both 'cross-sectional analysis weights' and 'longitudinal analysis weights' (Hill, 1992). Cross-sectional analysis weights can be used to obtain unbiased estimates of population statistics for a given year. Longitudinal analysis weights, on the other hand, can be used to estimate models of changes over time. In particular, the 1993 PSID longitudinal analysis weights assign nonzero weights only to individuals who were respondents during each of the preceding 5 years. The Canadian Survey of Income and Labour Dynamics also provides both longitudinal and cross-sectional weights (Statistics Canada, 1997). When using surveys with multiple sets of weights, consult survey documentation for advice on appropriate choice of survey weight.

Standard Errors

Although estimates of simple population parameters such as means and proportions can easily be constructed as weighted averages using survey weights, the corresponding standard error estimation procedures are not included in most standard statistical packages. When the data have been collected from a survey with a complex sample design, standard error estimates of survey statistics derived under simple random sampling assumptions generally underestimate the true standard error, resulting in confidence intervals that are too narrow and hypothesis tests that are too likely to reject the null hypothesis. In particular, most standard statistical packages can handle 'analytic' weights that are used in regression estimation when the data values themselves each have different (known) variances, and 'frequency' weights that are used to store data concisely by recording the number of times an observation is duplicated in the dataset rather than recording each observation individually, but these weights should not be confused with survey weights. Incorrectly treating survey weights as analytic weights or frequency weights will generally result in unbiased point estimates but underestimated standard errors. Moreover, ignoring the weights altogether and using a standard statistical package to perform an unweighted analysis of complex survey data will generally yield biased estimates of population parameters and underestimated standard errors. Furthermore, standard statistical packages do not account for stratification, cluster sampling, or adjustments such as post-stratification and raking. Brogan (1998) and Wang et al. (1997) illustrate some of the potential consequences of incorrectly analyzing survey data using standard statistical packages.

As a measure of the effect of the sampling design on the variance of survey estimates, some surveys report design effect estimates. The design effect (deff) (Kish, 1965: p. 162; Lohr, 1999: p. 239) measures the increase (or decrease) in variance obtained using the given sample design relative to the variance that would have been obtained if a simple random sample of the same size had been used. For example, Davis and Smith (1992: p. 41) report that the average design effect for 60 variables in the GSS is 1.76, with slightly larger design effects on average for demographic variables, which tend to have more clustering and smaller design effects, on average, for attitude variables. Similarly, Hill (1992: p. 67) reports design effects for estimates from the PSID ranging from 0.95 to 2.53, with most in the range 1.1–2.2. A design effect of 1.76 indicates that the variance of an estimate from the current design is 1.76 times greater than the variance that would have been obtained using a simple random sample of the same size. The design effect can be used to determine the 'effective sample

size' by dividing the actual sample size by the design effect. The effective sample size is the number of observations that would yield the same level of precision from a simple random sample. For example, a design effect of 1.5 implies that the precision obtained by sampling 1500 units under the current complex sampling design could be obtained by sampling only 1000 in a simple random sample design. The design effect does not, however, account for differential costs of the two sampling designs.

Several software packages are available to analyze data from complex multistage surveys. Summaries and reviews of these packages are provided by Lepkowski and Bowles (1996), Cohen (1997), Carlson (1998), and Zaslavsky (2000). Stata (StataCorp, 1999) and the latest release of SAS (An and Watts, 1998) are multipurpose statistical packages that include procedures for analyzing complex survey data. Because variance estimation calculations for sampling designs that use without-replacement unequal probability sampling are complex, most survey software packages approximate these variances using formulae appropriate for unequal with-replacement sampling. This approximation is usually acceptable since, for these survey designs, the resulting variance estimates will slightly overestimate the true variance, resulting in slightly conservative confidence intervals and hypothesis tests. Finally, survey software packages generally use variance formulae that are technically only appropriate when the survey weights represent only the sampling design and do not incorporate nonresponse or poststratification adjustments. A few packages (WesVarPC and VPLX, see Lepkowski and Bowles, 1996) use a variance estimation method call replication or resampling (Wolter, 1985: Chapter 2; Korn and Graubard, 1999: p. 29) that can incorporate the impact of nonresponse weighting adjustments and poststratification adjustments. To take advantage of these capabilities, data users must be provided with 'replicate weights' (e.g., Korn and Graubard, 1999: p. 34) by the data producers. For example, the US Census Bureau releases replicate weights for the Survey of Income and Program Participation.

Finally, many large-scale surveys provide generalized variance functions (Korn and Graubard, 1999: p. 218; Lohr, 1999: pp. 308–310) in summary reports of the survey data. To reduce publication costs and calculation effort, these surveys do not publish standard errors for every estimate in the summary report. Instead, generalized variance functions are provided to enable data users to calculate standard errors for their estimates of interest. These functions estimate the standard error of an estimate as a function of the estimate. These standard error estimates are very approximate and their results should be interpreted with caution. Direct calculation of standard error estimates using the raw data, survey weights, and other sampling design information is always preferable to using generalized variance functions. However, generalized variance functions permit standard error estimation when either the raw data or the sampling design information cannot be released for confidentiality reasons.

Confidence Intervals

When constructing confidence intervals for population parameters using survey data, it is usually assumed that survey estimates of means and proportions are approximately normally distributed, so that the usual normal confidence intervals or, for small sample sizes n, t-distribution intervals with $n - 1$ degrees of freedom are appropriate (Cochran, 1977: p. 27). For complex multistage sampling, the degrees of freedom for t-intervals is typically equal to the number of sampled PSUs minus a correction, c, where $c = 1$ for unstratified cluster sampling and c equals the number of strata for stratified cluster sampling (Korn and Graubard, 1999: p. 62). The normality approximation may break down for estimates of proportions that are very close to 0 or 1. In these situations, Korn and Graubard (1999: p. 65) provide approximations to exact binomial confidence intervals that can be used with data from complex multistage sampling schemes.

Statistical Modeling with Survey Data

Much has been written on the use of the sample design and weights when fitting statistical models such as linear regression, logistic regression, loglinear models, and survival models to survey data (Fienberg, 1980; Groves, 1989: Section 6.7; Little, 1991; Pfeffermann, 1993; Lohr and Liu, 1994; Winship and Radbill, 1994; Korn and Graubard, 1995; Lemeshow et al., 1998). In general, it is recommended to include, as explanatory variables in any regression-type analysis, all variables that are used in the design or the weighting of the survey. These variables include stratum indicators, cluster indicators, and demographics (such as age, sex, ethnicity, and education) that are used to construct the weights. It is thus important in such an analysis to know how the weights were constructed, not just their numerical values. If all these variables are included, one can fit the model without survey weights (see DuMouchel and Duncan, 1983; Korn and Graubard, 1999: p. 177). It may then be necessary to put the weighting information back into the model – after having estimated the parameters – to estimate population quantities of interest. For example, Gelman and Little (1997) present an example in which estimates are obtained for each of the states in the United States, summing over demographic categories, which requires the use of census demographic breakdowns for each state. Difficulties can arise when the number of clusters or strata is large relative to the sample size or when stratum or cluster indicators are not released in public-use data for confidentiality reasons. It can also make sense to perform both weighted and unweighted analyses (DuMouchel and Duncan, 1983; Groves, 1989: p. 290; Lohr, 1999: p. 365; *see also* Sample Surveys: Model-based Approaches). Large differences between the two analyses may indicate model misspecification.

Modeling is also used for 'small-area estimation' in which inferences are made about subsets of the population (e.g., small geographic regions or demographic segments) whose sample sizes are so small that simple weighted mean estimates are too variable to be useful. Hierarchical Bayes and related methods have been useful here (Fay and Herriot, 1979; Dempster and Raghunathan, 1987), and one area of ongoing research is combining these methods with classical weighting adjustments (Gelman, 2007). The method of multilevel regression and poststratification (Lax and Phillips, 2009) combines small-area estimation (using hierarchical modeling

to get estimates for small subgroups of the population via partial pooling) and population-level information to sum up to larger groups, for example, to estimate state-level opinions from national surveys.

Missing Data

In a sense, all sampling is about missing data, since the goal is to learn about the entire population from a subset. Usually, however, missing data in sample surveys refers to unit nonresponse, which occurs when some sampled units do not participate at all in the survey, either because they refuse or cannot be reached for interview, and item nonresponse, which occurs when a sampled unit responds to some but not all questions in the survey. Survey organizations usually adjust for unit nonresponse by weighting, as discussed earlier in this article.

Item nonresponse is typically handled in one of three ways (Little and Rubin, 1987). In 'complete-case' analysis, one works only with the data from respondents who provided responses to all questions of interest. 'Available-case' analysis is the other extreme, where, for each question, one uses all the responses in the data. Both these approaches have the serious problem that item nonresponses do not generally occur completely at random, so it can be misleading to simply ignore them (Rubin, 1976). A more flexible approach to item nonresponse is 'imputation,' filling in values for missing responses.

Imputation can be done in a number of ways, and for large-scale surveys, it is often performed by the survey organization itself. Missing values may be imputed using single or multiple imputations. In single imputation (Kalton and Kasprzyk, 1986; Little and Rubin, 1987: Section 4.5), a single value is imputed for each missing value. In multiple imputations (Rubin, 1987), m plausible values are imputed for each missing value to reflect the uncertainty about the missing data (usually m is between 5 and 10). These plausible values create m completed datasets that can each be analyzed separately as if they had complete response. Simple combining rules (Rubin, 1987: p. 76) can be used to combine results from each of these m separate analyses into one overall estimate along with its standard error. If data have been imputed using single imputation, special variance formulae (e.g., Rao, 1996) are needed to account for the extra variability introduced into survey estimates due to the uncertainty in the missing values. Most large-scale surveys are currently singly imputed, but multiple imputations is becoming more popular because of the relative ease of analyzing multiply imputed datasets compared to singly imputed data. For example, the US National Health and Nutritional Examination Survey plans to release a multiply imputed dataset (Schafer et al., 1993, 1996).

Related to imputation are various data-adjustment and correction procedures. For example, survey questions such as income that have occasional very high, unreliable responses can be 'topcoded' – that is, truncated at threshold values. Difficulties with analyzing topcoded data can sometimes be avoided by working with medians or quantiles (e.g., upper fifth, second fifth, etc.), as these are less sensitive than averages to extreme values.

Summary

Large-scale social surveys are an important source of information for a wide range of topics. In analyzing such surveys, it is important to be aware of the complexity of the sampling design and the data adjustments that are used by survey organizations, including weighting to adjust for differences between sample and population and imputation to fill in missing responses. For estimating population means and proportions, the analyst should calculate weighted averages, using survey weights. In regression analysis, it is best to include, among the predictors, the variables that are used in the design and the weighting. Hierarchical models can be used to obtain inferences for small subpopulations.

In general, simple standard error estimates, which assume simple random sampling, are too small because of stratification, clustering, and weighting. These calculations can often be adjusted reasonably well by using design effects reported in the survey documentation or in previous analyses. For more involved analysis, it is advisable to use statistical packages that are specifically designed to correctly handle complex survey data.

Abstract

Karl Lashley was the most important and influential American Scientist in the first half of the twentieth century in the development of modern biological psychology. He was born in Davis, West Virginia on 7 June 1890 and died in Poitiers, France on 7 August 1958. He obtained his PhD at Johns Hopkins with H.S. Jennings and also worked with Adolf Meyer and John B. Watson. Lashley developed the lesion-behavioral methodology to analyze brain substrates of learning and memory, and revolutionized the field. His analysis of the problem of serial order in behavior was a precursor of modern cognitive neuroscience. His critical analysis of all extant theories of brain, learning, and behavior, including his own, was so compelling that none of these theories survived. On the other hand, he contributed an extremely important empirical literature on the role of the visual cortex in visual discriminations, on recovery of function following brain injury, on the organization of thalamocortical projection systems, and on cortical cytoarchitectonics. 'Eminent psychologist with no earned degree in psychology, famous theorist who specialized in disproving theories, including his own, inspiring teacher who described all teaching as useless'.

It is probably fair to say that Karl Lashley was the most important and influential American scientist in the first half of the twentieth century in the development of modern biological (and even experimental) psychology. His work and writings had a profound influence on such fields as brain substrates of learning and memory, the study of serial behaviors, complex cognitive processes, and our understanding of basic brain organization, particularly of the cerebral cortex.

Karl Lashley was born in Davis, West Virginia on 7 June 1890. His parents were themselves successful – his father was variously a storekeeper, postmaster, banker, and mayor of Davis and his mother, energetic and intellectual with literary and artistic interests. Lashley grew up in Davis, except for a rather extraordinary trek; the family took to the gold rush in the Klondike in 1898–99.

Lashley was an only child and acknowledged a great debt to his mother for nurturing his intellectual interests. He had learned to read well by the age of four. His mother taught in a country school until Karl was born but maintained a center for adult education in her home where women (and Karl) came for instruction in such subjects as civics, Greek poetry, and drama.

As a boy Karl read widely from the extensive family library but also displayed great interest in plant and animal life, wandering through the local fields and woods, collecting butterflies, snakes, frogs and snails, and keeping pet mice and raccoons.

Karl entered a private school at the age of four and later attended public schools in Davis, where he graduated from high school at the age of 14. He entered the University of West Virginia but did not qualify as a freshman because his high school was not accredited. He spent a preparatory year which he felt was wasted. He initially planned to study Latin but was instead assigned English as a major. To fill a vacancy in his schedule he enrolled in a course in Zoology taught by John Black Johnston, a neurologist and the only teacher of zoology at the university. This course and Johnston had a profound influence on Karl. He later wrote that 'within a few weeks in his class I knew that I had found my life's work.'

Lashley received his BA at West Virginia in 1910. He then entered the master's degree program at the University of Pittsburgh as a teaching fellow. During his year there in biology, he attended a course in experimental psychology by Karl Dallenbach, a teaching fellow in psychology. To quote Dallenbach: 'Lashley's laboratory was on the floor above mine. Though he had never taken a course in psychology, he was permitted, because he was a fellow, to elect my laboratory course in experimental psychology. The class was small and we worked intimately together upon the various experiments. Lashley was intensely interested and was the outstanding student in the class—as one might expect being a graduate student in an undergraduate class, but he was more than a run-of-the-mine graduate student. He showed in that course the promise that he later fulfilled' (Beach, 1961, p. 170).

The following summer Lashley worked at the Carnegie Laboratories at Cold Spring Harbor, where he conducted basic studies on a ciliate. A very distinguished zoologist at Johns Hopkins, H.S. Jennings, was so impressed with this work that he offered Lashley a fellowship. At Hopkins, Lashley worked with Jennings on paramecia and completed a PhD thesis on inheritance in the asexual reproduction of Hydra (1914). Lashley took a minor in psychiatry with Adolf Meyer, a pioneering figure in biological psychiatry and another minor (in psychology) with John B. Watson. The influence of Watson on Lashley was profound.

In a letter written much later to Ernest Hilgard at Stanford, Lashley described taking a seminar with Watson in 1914. Watson called their attention in the seminar to the writings of Bechterev on conditioned reflexes, which they translated. 'In the spring I served as an unpaid assistant and we constructed apparatus and did experiments, repeating a number of their experiments. Our whole program was then disrupted by the move to the lab in Meyer's Clinic. There were no adequate animal quarters there. Watson started work with infants as the next best material available. I tagged along for awhile but disliked the babies and found me a rat lab in another building. We accumulated a considerable amount of experimental material

on the conditioned reflex that was never published. Watson sought the basis of a systemic psychology and was not greatly concerned with the reaction itself' (Hilgard, personal communication, 1984).

The conditioned reflex thus came to form the basis of Watson's behaviorism. Lashley, on the other hand, had become interested in the physiology of the reaction and the attempt to trace conditioned reflex paths through the central nervous system. At the end of his career, Lashley was reputed to have said that anyone who knows American psychology today (*c*. 1958) knows that its value derives from biology and from Watson.

During the period at Hopkins, Lashley worked with Shepherd Ivory Franz at St. Elizabeth's Hospital in Washington. Together, they developed a new approach to the study of brain mechanisms of learning and memory and published landmark papers on the effect of cortical lesions on learning in rats. From this time (1916) until 1929 Lashley systematically used the lesion method in the attempt to localize memory traces in the brain. Following Watson (and Pavlov), Lashley conceived of the brain as a massive reflex switchboard, with sequential chaining of input–output circuitries via the cerebral cortex as the basis of memory. This work culminated in his classic monograph *Brain Mechanisms of Intelligence* (1929). He was also President of the American Psychological Association that year. His presidential address, and his 1929 monograph, destroyed the switchboard reflexology theory of the brain function and learning as it existed at that time.

In complex mazes, rats were impaired in learning and memory in proportion to the degree of cerebral cortex destroyed, independent of locus. Lashley employed the terms 'mass action' and 'equipotentiality' more to describe his results than as a major theory. He did not deny localization of function in the neocortex; indeed, his work on visual discriminations strongly supported localization (see Lashley, 1942). Using anatomical and physiological methods, he was perhaps the first to demonstrate the point-to-point projection from the lateral geniculate nucleus to the visual cortex. Rather, he argued that the neural substrate for higher order memorial functions, he often used the term 'intelligence,' as in complex maze learning in rats, was widely distributed in the cerebral cortex. He did attempt to develop a theory of cortical field-like interference patterns as a mechanism to account for equipotentiality in perception and learning, but he found it wanting. 'He remarked that he had destroyed all theories of behavior, including his own' (Hebb, 1959, p. 149). Lashley was perhaps the most formidable critical thinker of his time, successfully demolishing all major theories of brain-behavior extant at the time, from Pavlov to the Gestalt psychologists, to his own views.

Lashley's influence was such that the field concerned with brain substrates of learning and memory went into decline for a period of years. The studies by Lashley had critics. Walter Hunter, for example, noted that the more cortex destroyed, the more sensory areas are destroyed and the fewer sensory cues are available to the animal. Part of the problem is that maze learning is a very complex task; the notion that a simple localized engram or memory trace could serve to code the memory for a maze, seems unrealistic today. In fact, simple memories do appear to have engrams that are quite localized in the brain: conditioning of discrete responses like eyeblink in the cerebellum and conditioned fear in the amygdala. The brain structure most involved in spatial learning and memory is not the neocortex but rather the hippocampus, at least in rats. However, Lashley's view is still held today in the sense that some cognitive scientists argue that complex memories are widely distributed in the brain. The jury is still out on this matter, no distributed memories having been found.

Near the end of his career, looking over his lifetime of research on memory, Lashley (1950) concluded that: 'This series of experiments yielded a good bit of information about what and where the memory trace is not. It has discovered nothing directly of the real nature of the memory trace. I sometimes feel, in reviewing the evidence of the localization of the memory trace, that the necessary conclusion is that learning is just not possible. It is difficult to conceive of a mechanism that can satisfy the conditions set for it. Nevertheless, in spite of such evidence against it, learning sometimes does occur' (pp. 477–478).

Lashley's positive contributions were extraordinary, including an insightful analysis of 'instinctive' behaviors, analysis of sexual behaviors, characterization of the patterns of thalamocortical projections, a rethinking of cortical cytoarchitectonics, etc. Lashley's first professional position was as instructor of psychology at the University of Minnesota (1917). Robert Yerkes was to become the chair of the psychology department there and arranged Lashley's hire. However, Yerkes became much involved in the organization of the National Research Council in Washington and did not move to Minnesota. Lashley left after 1 year, returning to Baltimore where he resumed his work with John Watson. Lashley returned to Minnesota in 1920, where he was promoted from instructor to full professor in 3 years. Lashley remained at Minnesota until 1926, when he moved to the University of Chicago.

In 1936 James B. Conant, then the new president of Harvard, appointed an ad hoc committee to find the best psychologist in the world. Lashley, then at the University of Chicago, was chosen and hired in 1937. He became Director of the Yerkes Laboratory of Primate Biology in Florida but maintained his Chair at Harvard, traveling to Cambridge once each year to give his 2-week graduate seminar. The roster of eminent psychologists and neuroscientists who worked with Lashley is without parallel.

Lashley was an extraordinary teacher, albeit most of his teaching was individual. He was of the view that those who need to be taught can't learn and those who can learn don't need to be taught. Following is a description of his teaching at Minnesota by a former student: 'I saw Karl for the first time when I was taking a General Psychology course. An assembly lecture was given to all psychology classes once every two weeks, with different professors giving one lecture to about 200 students. Karl, tall, lean, sardonic held up a frog, made the muscles jump, grinned at us and talked informally in his rather precise voice. We learned more in 40 minutes from him than we had from the other eight professors and we all filed out of the hall wanting to know when we could take a course from this thin, splendid lecturer, with the pince-nez on a black string. We quickly learned that we couldn't. He hated teaching formally and was available for only a few graduate students' (Beach, 1961, p. 182).

Although Lashley is not widely recognized as one of the sources for the development of the current field of cognitive

neuroscience, his extraordinary paper on the problem of serial order in behavior clearly anticipated this field (see Bruce, 1994).

'This is the essential problem of serial order: the existence of generalized schemata of action which determine the sequence of specific acts, acts which in themselves or in their associations have no temporal valence' (Lashley, 1951, p. 122).

Lashley never wrote directly about the nature of consciousness. According to his student Roger Sperry (personal communication) he was interested in the problem of consciousness but refused to write about it, considering it to be perhaps something of an epi- phenomenon. He did, however, speculate about the nature of mind: 'Mind is a complex organization, held together by interaction processes and by time scales of memory, centered about the body image. It has no distinguishing features other than its organization ... there is no logical or empirical reason for denying the possibility that the correlation (between mental and neural activities) may eventually show a complete identity of the two organizations' (Lashley, 1958, p. 542).

Lashley received essentially all the honors available to a psychologist: President of the American Psychological Association; election to membership in the Society of Experimental Psychologists; British Psychological Association; Harvey Society; US National Academy of Sciences; Royal Society, London (Foreign Member); American Philosophical Society; American Academy of Arts and Sciences; granted the Howard Crosby Warren Medal by the Society of Experimental Psychologists for outstanding scientific contributions to psychology; the Daniel Girard Elliot Medal in Zoology by the National Academy of Sciences and the William Baly Medal in Physiology from the Royal College of Physicians. About the only honor he did not receive is the Nobel Prize, and many felt he should have done so. Sir Francis Walshe, a most distinguished neurologist, gave the following tribute: '... one of the most brilliant exponents of those problems that include psychology and physiology of the brain. He moved in this difficult territory with an experimental flair, an intellectual poise, and a competence he shared with few. His contributions to science were of a major order, and lesser men than he have been Nobel Prize men' (Beach 1961, p. 191).

Frank Beach (1961) offered a favored tribute: 'Eminent psychologist with no earned degree in psychology. Famous theorist who specialized in disproving theories, including his own. Inspiring teacher who described all teaching as useless' (Beach, 1961, p. 163).

Karl Lashley died in Poitiers, France, on 7 August 1958.

Abstract

A 'latent variable' in a statistical model is a random variable that is unmeasured (although not necessarily unmeasurable). There are three main reasons for introducing latent variables into a statistical model. One reason is to include in the model features of interest that are not directly measurable, or were not measured. A second reason is that, in some circumstances, latent variables models can be used to construct estimators that are more efficient than those constructed from nonlatent variable models. A third advantage is that, in some circumstances, latent variables models can be used to construct estimators of manipulation statistics that are unbiased, unlike those constructed from nonlatent variable models. (A manipulation statistic is a statistic in a population in which some of the random variables have values externally forced upon them, e.g., as in a randomized experiment.) However, introducing latent variables into a model also introduces a host of modeling difficulties, including possibly making the model underidentified, and greatly complicating the search for the correct causal model (which in many cases is needed to construct a consistent estimator of manipulation statistics).

A 'latent variable' in a statistical model is unmeasured, although not necessarily unmeasurable. Many types of statistical models contain latent variables, including factor analytic models, item response models, some structural equation models, Rasch models, and finite mixture models. The section 'Linear Structural Equation Models' describes latent structural equation models, which are representative examples of latent variable models. (Latent structural equation models include factor analytic models as a special case. *See* Factor Analysis and Latent Structure Analysis: Confirmatory Factor Analysis and Factor Analysis and Latent Variable Models in Personality Psychology.) The section 'Introducing Latent Variables' describes the purpose of introducing latent variables into a model. The section 'Construction of Latent Variable Models' describes methods of constructing latent variable models, and problems that arise with the introduction of latent variables. The section 'Conclusion' is a brief summary, and The section 'Pointers to Literature' gives pointers to the literature.

Linear Structural Equation Models

There are several different methods of parameterizing structural equation models. The one described here is essentially the same as the one used in Bentler (1985). The variables in a linear structural equation model (SEM) can be divided into two sets, the 'error variables' or 'error terms,' and the substantive variables. The error terms are latent, and some of the substantive variables may be latent as well. A structural equation model consists of a set of structural equations, one for each substantive variable, and the distributions of the error terms; together these determine the joint distribution of the substantative variables. The structural equation for a substantive variable Xi is a linear equation with Xi on the left-hand side of the equation, and the direct causes of Xi plus an error term ε_i on the right-hand side of the equation. (In some representations, some substantive variables occur only on the right-hand side of structural equations and do not have a corresponding error variable.) A SEM contains information about both the joint probability distribution over the substantive variables, and about the causal relations between the substantive variables.

Figure 1 contains an example of a latent variable SEM that is a model of mathematical test scores discussed in Spirtes et al. (2001). The original data set came from Mardia et al. (1979). The test scores for 88 students in five subjects (Mechanics, Vector Algebra, Algebra, Analysis, and Statistics) are the measured variables. The latent substantive variables are Algebra Skill, Vector Algebra Skill, and Real Analysis Skill. The distribution of the test scores is approximately normal. In Model M of Figure 1, the free parameters are the linear coefficient a, b, c, and d, and the variances and means of the error terms ε_M, ε_V, ε_{Al}, ε_{An}, ε_S, δAl, δAn, and δV. (The coefficients in the structural equations for Mechanics, Algebra, and Statistics have been fixed at 1 to ensure identifiability, which is explained below.)

$$\textit{Mechanics} = 1 \times \textit{Vector Algebra Skill} + \varepsilon_M$$
$$\textit{Vector} = a \times \textit{Vector Algebra Skill} + \varepsilon_V$$
$$\textit{Algebra} = 1 \times \textit{Algebra Skill} + \varepsilon_{Al}$$
$$\textit{Analysis} = b \times \textit{Real Analysis Skill} + \varepsilon_{An}$$
$$\textit{Statistics} = 1 \times \textit{Real Analysis Skill} + \varepsilon_S$$
$$\textit{Vector Algebra Skill} = c \times \textit{Algebra Skill} + \delta_V$$
$$\textit{Real Analysis Skill} = d \times \textit{Algebra Skill} + \delta_{An}$$
$$\textit{Algebra Skill} = \delta_{Al}$$

Figure 1 Model M.

Structural equation models are a subset of graphical models (*see* Bayesian Graphical Models and Networks). Each SEM is associated with a graph (known as a path diagram) that represents the causal structure of the model and the form of the linear equations, where there is a directed edge from X to Y ($X \rightarrow Y$) if the coefficient of X in the structural equation for Y is nonzero (i.e., X is a direct cause of Y), and there is a bi-directed edge between the error terms ε_X and ε_Y if and only if the covariance between the error terms is nonzero. In path diagrams, latent substantive variables are enclosed in ovals, and measured variables are enclosed in rectangles.

SEMs and Probability Distributions

Let θ be a set of parameter values for SEM N that contains just the parameter values for the linear coefficients that have not been fixed, and the covariances of the error terms (i.e., the means of the error terms are not included in θ). In a SEM N, θ determines a covariance matrix over the substantive variables which will be denoted by $\sum(\theta)$ (Bollen, 1989). A covariance matrix $\sum$ is represented by a SEM N if there is a set of parameter values θ for the parameters in N such that $\sum(\theta) = \sum$. From the joint distribution over the variables, it is also possible to calculate conditional distributions, e.g., the conditional covariance matrix is just the partial covariance matrix if the error terms are normally distributed.

If there are no two distinct sets of parameter values θ and θ' for a model N such that $\sum(\theta) = \sum(\theta')$ then the model is *identified*. If a model is identified then there are a variety of methods for estimating the parameters, and a number of programs that perform the estimation (Bentler, 1985; Jöreskog and Sörbom, 1998). Also, if a model is identified, it is possible to evaluate it by testing it against a nested model using a χ^2 test with the appropriate degrees of freedom, or by assigning one of a variety of kinds of scores to the model (Bentler, 1985; Jöreskog and Sörbom, 1998).

In addition to implying a distribution over the substantive variables in the model, a SEM implies the total effect of each variable on each other variable (Bollen, 1989). A SEM is *acyclic* when its path diagram contains no directed path from a variable to itself. For acyclic SEMs, there is a simple rule for calculating the total effect of A on B. Suppose that the edge $X \rightarrow Y$ in the path diagram is labeled by the linear coefficient of Y in the structural equation for X (e.g., the edge from *Real Analysis Skill* to *Analysis* is labeled by b). Then the total effect of A on B is the sum over all directed paths from A to B, of the product of the edge labels along each path (e.g., the total effect of *Algebra Skill* on *Real Analysis* is $b \times d$).

The meaning of the total effect of A on B can be described as follows. In contrast to conditioning, a manipulated probability distribution is not a distribution in a subpopulation of an existing population, but is a distribution in a (possibly hypothetical) population formed by externally forcing a value upon a variable in the system. For example, among the subgroup of students who scored above 65 on the *Analysis* test (which was quite a high score), the mean *Statistics* score was above the mean for the whole class. On the other hand it is possible to manipulate the scores of all of the students by teaching them the answers to the questions on the *Analysis* test before they take it. In that case the mean *Statistics* score would remain the same for the whole class. So the mean *Statistics* score conditional on the *Analysis* score being above 65 would not equal the mean *Statistics* score, given that the score of the *Analysis* test was manipulated to be above 65. The total effect of A on B is just the change in B resulting from a manipulation that forces a unit change in A.

Of course, how an actual manipulation would affect other variables would depend upon how the system is manipulated. If the *Analysis* test score were changed by practice and studying to improve *Real Analysis Skill*, then one might expect that the *Statistics* test score might change as well. In that case, the manipulation has changed *Statistics*, but not through the mechanism of changing the *Analysis* score. The total effect of *Analysis* on *Statistics* is the resulting change in *Statistics* due to a kind of ideal manipulation of *Analysis*, in which the only variable in the system directly affected by the manipulation of *Analysis* is *Analysis* itself. Strotz and Wold (1960) suggested that an ideal manipulation of a variable X to a fixed value x could be represented by replacing the structural equation for X with a new equation $X = x$. The manipulated distribution is then just the distribution for the new structural equation model. Figure 2 shows the model that results from the manipulation of *Analysis*. The path diagram of the manipulated population is formed by breaking all of the edges into the manipulated variable.

Unlike a conditional distribution which is completely determined by the population joint distribution, a manipulated distribution depends upon both the population joint distribution and the true path diagram (or structural equations). In particular, two models with different path diagrams can represent the same set of joint probability distributions, but differ in their predictions of the total effect of manipulating a variable. Figure 3 shows an alternative to Model M of Figure 1, where the edge between *Real Analysis Skill* and *Algebra Skill* has been reversed. In Model M, the total effect of *Algebra Skill* on *Real Analysis* is nonzero, while in Model M′, the total effect of *Algebra Skill* on *Real Analysis* is zero. However, both M

$$\textit{Mechanics} = 1 \times \textit{Vector Algebra Skill} + \varepsilon_M$$
$$\textit{Vector} = a \times \textit{Vector Algebra Skill} + \varepsilon_V$$
$$\textit{Algebra} = 1 \times \textit{Algebra Skill} + \varepsilon_{Al}$$
$$\textit{Analysis} = 100$$
$$\textit{Statistics} = 1 \times \textit{Real Analysis Skill} + \varepsilon_S$$
$$\textit{Vector Algebra Skill} = c \times \textit{Algebra Skill} + \delta_V$$
$$\textit{Real Analysis Skill} = d \times \textit{Algebra Skill} + \delta_{An}$$
$$\textit{Algebra Skill} = \delta_{Al}$$

Figure 2 Model M after *Analysis* is manipulated to 100.

Figure 3 Model M.

and M′ represent the same set of distributions over the substantive variables. If Model M′ were considered to be compatible with background knowledge, the fact that M′ passes a statistical test or is assigned a high score is not sufficient evidence that M′ can be used for calculating total effects; it is also important to know whether there are any other plausible models compatible with background knowledge (such as M) that would also pass a statistical test or receive a high score, and predict a different total effect.

Introducing Latent Variables

There are three main reasons for introducing latent variables into a model. The first is that there may be variables of interest that either were not measured, or cannot be measured without error. The second is that a latent variable model may be necessary in order to represent correctly both the probability distribution over the measured variables, and the total effects that the measured variables have on each other. The third is that a latent variable model may be a more parsimonious representation of the distribution over the observed variables than any model without latent variables.

Measurement Error

Whenever there are measurement errors, the actual measurements are observed, but the quantity of interest that is being measured is a latent variable. For example, in Figure 1, *Algebra Skill*, *Real Analysis Skill*, and *Vector Algebra Skill* are measured indirectly by test scores. The test scores are not perfect measures of the corresponding latent quantities, but are also dependent on the error terms, i.e., there is measurement error in this model. Hence *Algebra Skill*, *Real Analysis Skill*, and *Vector Algebra Skill* are latent variables. If the goal is to estimate the total effect of *Algebra Skill* on *Statistics*, and the variance of ε_{Al} is not zero, then regressing *Statistics* on the measured variable *Algebra*, instead of on the latent variable *Algebra Skill*, gives a biased estimate of the total effect. However, under the assumption that the latent variable Model M is correct, estimations of the parameters of M can be used to calculate an unbiased estimate of the effect of *Algebra Skill* on *Statistics*.

Representing Causal Relationships Between Variables

The second main reason for introducing latent variables into a model is to represent correctly the total effects of the variables

Figure 4 SEMs without latent variables.

Figure 5 A parsimonious latent variable model.

upon each other. Suppose that Model M is the correct representation of the causal relations between the variables in the path diagram. In that case, the total effect of *Analysis* on *Statistics* is zero, the total effect of *Statistics* on *Analysis* is zero, but *Analysis* and *Statistics* are correlated. The possible SEMs (with no correlated errors) when there are no latent variable and only two measured variables *Analysis* and *Statistics*, are shown in Figure 4. None of these nonlatent variable models correctly represents both the correlation between *Analysis* and *Statistics*, and the zero total effects of each variable on the other. So in this case, a latent variable model is needed for the correct representation.

A bi-directed edge between the ε_{Al} and ε_S also correctly models the probability distribution and the total effects and does not explicitly introduce a latent variable that is a direct cause of both *Analysis* and *Statistics*; however, it does introduce such a latent variable implicitly. Assuming that a correlation between ε_{Al} and ε_S is produced either by ε_{Al} causing ε_S, ε_S causing ε_{Al}, or some third latent variable causing both of them, a bi-directed edge between ε_{Al} and ε_S also implies that there is some latent variable (possibly ε_{Al} or ε_S) that is a direct cause of both *Analysis* and *Statistics*.

Parsimonious Models

In some cases a latent variable model provides a more parsimonious (i.e., fewer parameters and higher degrees of freedom) representation of a distribution than any nonlatent variable model that represents the same distribution. Consider the model in Figure 5, where one latent variable (e.g., *IQ*) causes many measured indicators (e.g., various intellectual tasks.) It follows from results in Spirtes et al. (2001) that the latent variable model is more parsimonious than any other SEM nonlatent variable model that represents the same distribution (assuming all of the parameters of the nonlatent variable model are not constrained). Other things being equal, from a small sample size, the more parsimonious latent variable model could be used to provide a prediction of xn (e.g., grades in first year in college) from $x1, \ldots, xn - 1$ (e.g., scores on many different kinds of tests) that has a smaller mean squared error than any nonlatent variable model.

Construction of Latent Variable Models

Construction of SEMs often proceeds through a combination of the application of background knowledge with either

nonautomated or automated searches through the space of alternatives. The searches look for a model or a set of models with high posterior probabilities (*see* Bayesian Statistics), or high scores, or that pass a statistical test. Even without latent variables, the problem is a difficult one because the space of models to be searched grows exponentially with the number of variables. The search space may be constrained by background knowledge, but it is still typically enormously large.

Allowing latent variables into models makes the problem of constructing good models even more difficult. This is because estimating, testing, scoring, and searching for latent variable SEMs is fundamentally more difficult than the corresponding operations for acyclic directed graph SEMs (i.e., SEMs without latent variables, cycles, or correlated errors). The space of possible acyclic directed graph SEMs is finite, but the space of latent variable models is infinite. An acyclic directed graph SEM is always identified. A SEM with latent variables may not be identified, and the only known algorithm for determining if it is identified has a running time that grows exponentially with the number of variables. It is always easy to calculate the number of degrees of freedom for an acyclic directed graph SEM, but it is often difficult to calculate the number of degrees of freedom for a SEM with latent variables (Geiger and Meek, 1999).

While the estimation, testing, and scoring problems with latent variable models have been solved for special cases, and there are heuristic rules for other cases (Bollen, 1989), practical general solutions are not available.

Conclusion

There are three main reasons for introducing latent variables into models: using latent variables can lead to a more parsimonious model that improves prediction; when there is measurement error the natural representation of the quantities of interest is as latent variables; in some cases the only correct representation of the joint distribution of the observed variables and of the total effects of variables on each other is with models that contain latent variables (or bi-directed edges which imply the existence of latent variables).

While latent variable models have some advantages over nonlatent variable models, construction of a latent variable model is often more difficult than construction of nonlatent variable models. It is generally more difficult to estimate, test, score, and search for latent variable models than for nonlatent variable models.

Pointers to Literature

Sewell Wright (1921) introduced a form of structural equation model called path models. Bollen (1989) provides an overview and a brief history of linear structural equation models with latent variables, and Bartholomew and Knott (1999) describe a wide variety of latent variable models. Rubin (1977) discusses manipulations, which are also discussed in Spirtes et al. (2001), Pearl (1995), and Pearl (2000). Heckerman et al. (1999) and Spirtes et al. (2001) discuss the causal interpretation of latent variable models and describe a variety of automated search techniques. Acyclic directed graph structural equation models are special cases of Bayesian networks and graphical models.

Lateralization of Language as Demonstrated by Brain Imaging Procedures

Brigitte Stemmer, Université de Montréal, Montreal, QC, Canada; and Brock University, St. Catherines, ON, Canada

Published by Elsevier Ltd.

Abstract

Are statements such as 'Language is in the left hemisphere,' 'The first language is in the left and the second in the right hemisphere,' 'The brain of children recovers language perfectly after brain damage,' 'The adult brain cannot recover language functions and chronic aphasia does not improve over time,' 'Language functions are more lateralized to the left in men and more bilaterally in women' truths or myths? This article will discuss these and other issues related to the contribution the left and right hemispheres make to certain aspects of language. As will be shown, there is not always a straightforward answer to seemingly simple questions.

Introduction

Hemispheric asymmetry or laterality can be found across processing domains and contemporary species. Anatomical asymmetry refers to asymmetries concerning the brain structure and functional asymmetry (often referred to as lateralization) relates to domains such as perception, attention, motor control, memory, emotion, and language. It must be understood that hemispheric asymmetry is not an all or nothing phenomenon but rather operates on a continuum. Even if one hemisphere is dominant in performing a task or processing information, the other hemisphere usually has at least some competence in these domains (Hellige, 2008).

The notion that the left cerebral hemisphere deals with language is usually associated with the nineteenth-century neurologists Paul Broca and Carl Wernicke. Based on the observation that some patients with lesions on the left side of their brain showed language problems, speech production was associated with the *left* frontal region of the brain (left posterior inferior frontal gyrus, Broca's region) and speech perception with the *left* temporal region of the brain (left posterior superior temporal gyrus, Wernicke's region) (see Figure 1). The consequences of these landmark postulates are still present today and are reflected, for example, in the well-known language impairments called Broca's aphasia or Wernicke's aphasia.

Since the early lesion studies with brain damaged patients, the advent of functional neuroimaging techniques (*see* Functional Brain Imaging of Language processes) made it possible to identify the hemisphere and the regions therein that are active while a person is performing a task. As will be seen below, not all neuroimaging studies support the findings of lesion or behavioral studies. One reason is that while some of these neuroimaging techniques can provide relatively accurate information on where in the brain something happens, they do not tell us what the function or role of the activated hemisphere or brain region is, or how or whether these regions interact with other brain regions. Assigning functions or roles to an activated brain region is ultimately an interpretation by the researcher usually based on clever experimental designs and integration with findings from previous research. As pointed out by Petersen and Fiez (Petersen and Fiez, 1993: 513), it should not be forgotten that "A functional area of the brain is not a task area; there is no 'tennis forehand area' to be discovered. Likewise, no area of the brain is devoted to a very complex function; 'attention' or 'language' is not localized in a particular Brodmann area or lobe. Any task or 'function' utilizes a complex and distributed set of brain areas." Another issue the reader should be aware of is that the majority of neuroimaging studies has investigated language at the word level and, in comparison, there are relatively fewer studies investigating the sentence level and even fewer studies at the text or discourse level. In addition, although the way language is represented in the brain and the way it is processed are two different issues, this distinction is not always reflected in neuroimaging studies.

Considering these limitation, instead of talking about the lateralization of language in general, it would thus be more accurate to talk about the contribution the hemispheres make to *specific aspects* of language representation and processing. (For an overview of the language network in the left hemisphere and the anatomical regions referred to in the text see Figure 1.)

Lateralization at the Word Level

Imagine that you read a string of symbols such as *ptakopgx* (a non word), *siglowark* (a pseudoword), or *house* (a word). With astonishing speed, about 200–250 ms after seeing these symbols or hearing the corresponding sounds, your brain has determined whether this is a nonword, a word that does not make sense such as a pseudoword or a known word. Approximately 400 ms after reading or hearing a word, your brain has assigned some meaning to it. Which regions in the brain are implicated in these fast processes and is one hemisphere more implicated than the other? The classical language model advanced by Broca and Wernicke assigned language processing (words, sentences) to the left hemisphere and was based on the observation of a few patients and the study of their postmortem brains. More than 100 years after Broca's and Wernicke's famous insights, the first language study was published using positron emission tomography (PET) that allowed 'watching' which brain areas were active during auditory and visual word processing in healthy subjects (Petersen et al., 1988; Petersen and Fiez, 1993). These early and also later neuroimaging studies only partially confirmed the classical model. Summarizing the results of the numerous

Figure 1 Anatomical and cytoarchitectonic details of the left hemisphere. The different lobes (frontal, temporal, parietal, and occipital) are marked by colored borders. Major language-relevant gyri (IFG, STG, MTG) are color coded. Numbers indicate language-relevant Brodmann Areas (BA), which Brodmann (1909) defined on the basis of cytoarchitectonic characteristics. The coordinate labels superior/inferior indicate the position of the gyrus within a lobe (e.g., superior temporal gyrus) or within a BA (e.g., superior BA 44; the superior/inferior dimension is also labeled dorsal/ventral). The coordinate labels anterior/posterior indicate the position within a gyrus (e.g., anterior superior temporal gyrus; the anterior/posterior dimension is also labeled rostral/caudal). Broca's area consists of the pars opercularis (BA 44) and the pars triangularis (BA 45). Located anterior to Broca's area is the pars orbitalis (BA 47). The frontal operculum (FOP) is located ventrally and more medially to BA 44, BA 45. The premotor cortex is located in BA 6. Wernicke's area is defined as BA 42 and BA 22. The primary auditory cortex (PAC) and Heschl's gyrus (HG) are located in a lateral to medial orientation. Friederici, A.D., 2011. The Brain Basis of Language Processing: From Structure to Function. Physiological Reviews 91, 1357–1392.

neuroimaging studies that have since then been published is difficult due to different experimental paradigms and stimuli. Vigneau and colleagues (Vigneau et al., 2006, 2011) took on this challenging task and statistically contrasted and combined results from neuroimaging studies investigating mostly single word processing but also some sentence processing in healthy subjects. These meta-analyses showed that not only the left hemisphere but also the right hemisphere activated in single word processing albeit to a much lesser extent. Right-hemisphere activation was found in about one-third of the studies and this activation was most commonly accompanied by left-hemisphere activation. This has been interpreted as supporting the view that the right hemisphere involvement is dominated by interactions between the two hemispheres. In more than two-thirds of the studies, left-hemisphere activation was reported mostly without concurrent activation of the right hemisphere thus suggesting that left hemisphere involvement occurs mainly within the left hemisphere without much interaction with the right hemisphere (Vigneau et al., 2011). It was further noted that right-hemisphere participation in frontal brain regions was not always specific for a given language component suggesting that other cognitive processes such as working memory were also recruited by the verbal tasks.

After this global overview, we will now look in more detail at the contribution of the left and/or right hemisphere in response to specific processing tasks or demands.

Perceptual, Phonological, and Motor processing

When we perceptually process visual material (e.g., passively reading words), auditory material (e.g., listening to words), or when we acoustically analyze incoming speech sounds, regions in both hemispheres are recruited (specifically extrastriate occipital cortices, primary auditory cortices, and temporal brain regions including and surrounding the primary auditory cortex, respectively) (Petersen and Fiez, 1993; Price, 2012). Both hemispheres (especially motor regions and other regions surrounding Broca's area) are also activated when the task involves motor output of language and articulatory coding such as repeating words aloud. In short, processing related to word perception, acoustic analysis of speech sounds and articulation recruits both hemispheres. This, however, does not mean that the regions activated in both hemispheres are specific to speech; it has been shown that they also activate in response to other nonspeech material.

Regions of the left hemisphere alone (temporoparietal and cingulate regions) seem to be implicated in phonological coding processes (Petersen and Fiez, 1993). Other functions that have been associated with left lateralization only are acoustic complexity of speech (anterior part of superior temporal cortex), disambiguation of speech sounds (frontal and premotor areas), and the functional integration of acoustic processing (Price, 2012).

Lexicosemantic Processing

There is more to understanding or producing language than perceptual or phonological processes. We must also assign meaning (semantics) to words (lexis) and the question thus is what the contribution of each hemisphere is to lexicosemantic processing. Generally, most imaging studies support the view that lexical semantic knowledge is widely distributed in the brain with the left hemisphere being more involved than the right hemisphere (Binder et al., 2009; Vigneau et al., 2006, 2011; **Figure 2**). Activation of the left hemisphere alone was reported in most tasks that implicated reading words or listening to words for semantic content. Other tasks targeting semantic word processing such as word retrieval, word generation (*Name everything you can buy in a supermarket*), or word categorization also activated the left hemisphere, and especially left frontal brain regions (pars opercularis and orbitalis; dorsomedial prefrontal cortex) (Binder et al., 2009; Vigneau et al., 2006). Comparing words with different semantic content (e.g., reading words versus pseudowords; categorization of written words) showed activations in left temporal brain regions (posterior temporal gyrus). It was suggested that these activations are related to letter and grapheme processing in conjunction with the phonological network operational during reading (Vigneau et al., 2006). When associating meaning with words, one may also ask whether the *type* of meaning encoded in the words influences hemisphere activation. Many (but not all) non-imaging studies have suggested that abstract words (such as *creativity*) are processed in the right hemisphere and concrete words (such as *bottle*) in the left hemisphere. Although this has been supported by studies using the transcranial magnetic stimulation technique (TMS) (Hartwigsen and Siebner, 2011), the issue surrounding abstract and concrete concepts may also entail perception, action, and emotional systems which, in turn, would influence hemisphere activation (for a discussion see Kiefer and Pulvermüller, 2012). As it stands now, the issue needs further clarification.

In addition to frontal and anterior temporal regions, posterior temporal, and parietal regions have also been associated with semantic processing. The left fusiform gyrus, a region in the left temporooccipital brain area and best known for its implication in face recognition, has been related to the semantic

Figure 2 The diagrams show the large-scale semantic network of the human brain (a) and the probable homologous network in the macaque monkey brain (b). The green lines show the connections between different brain regions in the macaque monkey brain. Compared to the human semantic system, the cortical networks in the macaque monkey brain are strikingly similar in location and function (for details see Binder et al., 2009). Figure taken from Binder, J.R., Desai, R.H., Graves, W.W., Conant, L.L., 2009. Where is the semantic system? A critical review andmeta-analysis of 120 functional neuroimaging studies. Cerebral Cortex 19, 2767–2796.

processing of words and pictures (Vigneau et al., 2006). The parietal cortex of both hemispheres, and specifically the angular gyrus as one of the most consistently activated regions in the left hemisphere, has been viewed as a high-level integration area that occupies a top position in the processing hierarchy underlying concept retrieval and conceptual integration in both hemispheres (Geschwind, 1965; Binder et al., 2009; Vigneau et al., 2006). Some structures in both hemispheres, and especially the posterior cingulate gyrus and the hippocampal system, seem to act as an interface between semantic retrieval systems and brain systems that encode episodic information (Binder et al., 2009). Although activation of both hemispheres has been observed, left hemisphere activation is nevertheless frequently dominant.

Taken together, processing related to word perception, acoustic analysis of speech sounds and articulation relies on both hemispheres. The processing of phonological codes, acoustically complex speech and its functional integration, and the disambiguation of speech sounds seem to rely solely on the left hemisphere. While right-hemisphere activation can be observed with lexicosemantic processing, it is nevertheless the left hemisphere that seems dominant. The degree to which the two hemispheres are involved depends on the type of processing, the material that is being processed and the implication of other cognitive systems (such as attention and memory). It should be mentioned that although most studies related brain activation to semantic word processing, it has nevertheless been difficult to tease apart what is purely semantic processing and what is due to increased task demands and thus increased involvement of attention and memory networks, or phonological processing demands (Binder et al., 2009).

Lateralization at the Sentence Level

Language usually occurs as a stream of speech forming utterances which, in turn, are made up of words that may string together to form sentences. What is the contribution of each hemisphere in sentence or syntactic processing? This is not an easy question to answer. For one thing, most studies use sentences that compare meaningful complex sentences (e.g., *Sophia, who had a broken leg, was given a lift home by Peter*) with syntactically simpler sentences (*He gave her a lift home*) or with nonmeaningful sentences (*Mo soodled lorn en saweek*). This makes the distinction between syntactic and semantic processing components difficult (Cappa, 2012; Vigneau et al., 2006). In addition, effort and processing load may also play a role and involve other systems such as attention or memory. Other issues concern methodological decisions (e.g., the resolution power of the scans; the type of analysis; the focus on the processing or the linguistic material involved). Considering these limitations, it is not surprising that meta-analyses report activation of largely overlapping brain regions during syntactic and semantic processing (Vigneau et al., 2006, 2011). About half of the studies included in a meta-analysis investigating sentence and text processing tasks reported bilateral activation and the other half left-hemisphere activation only (Vigneau et al., 2011). Bilateral activation was seen in response to mental imagery with auditory sentences, plausibility judgment on the semantic content of a sentence, and comparison of complex to simple sentences (Vigneau et al., 2011). When the left hemisphere alone was activated, two regions in the frontal lobe seemed dedicated to sentence processing. These regions were identified in the middle frontal region (left posterior middle frontal gyrus) and in Broca's area (inferior frontal region, specifically the dorsal part of the pars opercularis). As the middle frontal gyrus is also activated during working memory processes, it was suggested that its recruitment in language tasks was related to working memory implicated in the comprehension of complex linguistic material rather than solely to sentence processing (Vigneau et al., 2006). The left inferior frontal gyrus, which houses Broca's area, is the other region that seemed dedicated to syntactic processing. Aside from the frontal lobe, the temporal lobes of the left hemisphere also activate during sentence processing. In fact, Vigneau et al. (2006) found that the left temporal cortex was more frequently activated in sentence processing (and overlapping with semantic regions) than the left frontal cortex.

Processing spoken sentences involves not only processing syntactic and semantic information but also acoustic features that are used to express linguistic prosody such as intensity, vocal pitch, rhythm, or rate of utterance. Linguistic prosody is mainly expressed by intonation, that is rising and falling variations in pitch sequences within speech, and is crucial for the interpretation of sentences (for example, distinguishing questions from nonquestions in English or extracting lexical meaning in tonal languages like Chinese). Most lesion studies have assigned a special role to the right hemisphere for processing suprasegmental prosody. Neuroimaging studies support this view and specify that the right hemisphere is involved in the processing of pitch information during sentence processing (Gandour et al., 2000, 2004; Plante et al., 2002; Minagawa-Kawai et al., 2011). If, however, pitch is used to distinguish lexical meaning (as in tonal languages), then a left-hemisphere processing bias emerges (Minagawa-Kawai et al., 2011).

To sum up, there is a large overlap of brain regions that activate during syntactic as well as semantic processing. This is not surprising considering the difficulties to clearly distinguish syntactic and semantic processing components. Bilateral activation is frequently observed in response to tasks that involve metacognitive judgments on sentence characteristics or complexity issues such as comparing complex and simple sentences. Some brain regions in the frontal lobe (including Broca's area) seem dedicated to syntactic processing although it seems that temporal regions in the left hemisphere are more frequently activated than frontal regions. The right hemisphere is dominant in processing linguistic prosody in nontonal languages.

Lateralization at the Pragmatic Level

Until now we have discussed lateralization of language at the word and sentence level without paying much attention to the context in which language is uttered. When we communicate in real life, however, we use language as action performed with words. The meaning of words (and larger linguistic units) is not viewed as an isolated entity but as an entity that gets

meaning by interpreting it in the context in which it occurs. An utterance such as *Same procedure as last year* may be humorously or ironically uttered to refer to the repetitive gathering for New Year's dinner or refer to the annual changing of my winter tires. What the speaker conveys with this utterance depends on, for example, the context, the situational circumstances and the listener's interpretation. The way we use these linguistic (as well as nonlinguistic) signs in interaction for the purpose of communication has been referred to as pragmatics, and the underlying brain correlates and processes that bring about pragmatic behavior have been coined neuropragmatics. Based on findings from patients whose right hemisphere is damaged and who subsequently show problems with different aspects of pragmatics, it has traditionally been assumed that pragmatics is the realm of the right hemisphere. With the advent of brain imaging techniques, this assumption has been called into question. Two aspects of pragmatics have received particular attention, that is the comprehension of text and discourse and of figurative language.

Text and Discourse Comprehension

One aspect of text comprehension that has been investigated with brain imaging are the neural substrates underlying coherence building, that is the processes that link the elements of a text in a meaningful way. For example, the following two utterances form a coherent text: (1) *The court convicted him to lifelong imprisonment;* (2) *The victim was brutally tortured and killed*. We link these utterances in a meaningful way by making inferences from our knowledge of the world (murder is a crime that is punished). Brain imaging studies investigating various types of coherence building report different findings. Some describe right hemisphere, some left hemisphere, and some bilateral activation. These discrepancies are possibly due to the different types of coherence and inferences investigated and differences in experimental paradigms (Ferstl, 2010; Stemmer, 2013).

Figurative Language

An area of research that has been the focus of numerous brain imaging studies is the way we communicate the 'unsaid' as reflected in metaphors or other figurative language (irony, sarcasm, idioms, proverbs). Traditionally, it was assumed that the processing mechanisms underlying figurative (*He lives on the moon*) and nonfigurative language (*He lives in Petersburg*) are different and that this difference is reflected in different hemisphere activation: nonfigurative language is processed by the left hemisphere and figurative language by the right hemisphere. While numerous lesion studies supported these hypotheses, no clear-cut picture has emerged from neuroimaging studies. Some studies report left hemisphere activation only, while others report either right or bilateral activation (for summaries see Bohrn et al., 2012; Schmidt and Seger, 2009; Ferstl, 2010). Heterogeneity of the experimental paradigms, individual variability and analysis methods are likely reasons for these discrepant findings. Despite these heterogeneities, researchers have attempted to find convergence. In a qualitative review, it was suggested that for metaphor processing the left hemisphere is activated when frozen, conventional or familiar metaphors are used and the right hemisphere activates when novel metaphors are used possibly due to nonfamiliarity and processing difficulty (Schmidt and Seger, 2009). In a quantitative review, bilateral activation with a bias to the left hemisphere was reported for figurative language when compared to literal language (Bohrn et al., 2012). This is surprising as numerous individual studies do report right hemisphere activation. It is possible that the meta-analysis did not produce a statistically significant activation cluster in the right hemisphere because many different regions activated in the right hemisphere. It was further reported that novel metaphors activated a bilateral network and this was interpreted as indicating processes of set-shifting and hypothesis generation. Familiar idioms or proverbs recruited the right hemisphere while the processing of irony and sarcasm activated prefrontal regions in both hemispheres and frontotemporal regions in the right hemisphere only (Bohrn et al., 2012). As other studies have shown that these regions are frequently activated in theory of mind and mentalizing tasks (that is recognizing the intentions and desires of others), it was suggested that irony and sarcasm rely more on theory of mind and mentalizing functions compared to the other types of figurative language.

Generally, it is difficult to reconcile the numerous brain imaging studies. What seems to emerge is that figurative and nonfigurative language share similar language networks in the left hemisphere – possibly including the default language network that is active whenever linguistic material is processed. In addition, depending on the type of stimuli, the task demands and characteristics of the listener, figurative language will recruit networks in the right hemisphere possibly reflecting other nonlinguistic processing mechanisms (such as attention, memory, organization and integration of information, and so forth).

Brain Connectivity within the Left Hemisphere

As detailed in the previous sections, the left hemisphere has a dominant role in the functional neural networks for processing different aspects of language, especially at the word and sentence level. Within the left hemisphere, the language network includes frontal regions (Broca's area in the inferior frontal gyrus) and temporal regions (Wernicke's area in the superior temporal gyrus) (see **Figure 3**). For these regions to be functional, they need to correspond with other brain regions via so-called fiber tracts or pathways (white matter). There is general consensus that major pathways connecting important language areas run above (dorsally) or below (ventrally) the Sylvian fissure, which separates the frontal from the temporal lobe (Catani et al., 2005; Catani and Mesulam, 2008; Friederici, 2009, 2012; Saur et al., 2008, 2010; Weiller et al., 2009). Some of these pathways show hemispheric asymmetries already in early infancy (Geng et al., 2012). For example, it has been shown that the arcuate fasciculus connecting temporal with frontal brain regions is already asymmetric in the first 2 years of life. It is still a matter of debate where exactly these fiber tracts start and end and how they branch out. While most researchers agree that there is a ventral stream for sensory percept and a dorsal stream for meaning, the details of their functional significance is still

Figure 3 The cortical language circuit (schematic view of the left hemisphere). The major gyri involved in language processing are color coded. In the frontal cortex, four language-related regions are labeled: three cytoarchitectonically defined Brodmann [39] areas (BA 47, 45, 44), the premotor cortex (PMC) and the ventrally located frontal operculum (FOP). In the temporal and parietal cortex the following regions are labeled: the primary auditory cortex (PAC), the anterior (a) and posterior (p) portions of the superior temporal gyrus (STG) and sulcus (STS), the middle temporal gyrus (MTG) and the inferior parietal cortex (IPC). The solid black lines schematically indicate the direct pathways between these regions. The broken black line indicates an indirect connection between the pSTG/STS and the PMC mediated by the IPC. The arrows indicate the assumed major direction of the information flow between these regions. During auditory sentence comprehension, information flow starts from PAC and proceeds from there to the anterior STG and via ventral connections to the frontal cortex. Back-projections from BA 45 to anterior STG and MTG via ventral connections are assumed to support top-down processes in the semantic domain, and the dorsal back-projection from BA 44 to posterior STG/STS to subserve top-down processes relevant for the assignment of grammatical relations. The dorsal pathway from PAC via pSTG/STS to the PMC is assumed to support auditory-to-motor mapping. Furthermore, within the temporal cortex, anterior and posterior regions are connected via the inferior and middle longitudinal fasciculi, branches of which may allow information flow from and to the mid-MTG. Friederici, A.D., 2012. The cortical language circuit: from auditory perception to sentence comprehension. Trends in Cognitive Sciences 16, 262–268.

a matter of debate. Ventral pathways connect the left temporal cortex with the left prefrontal cortex via the extreme fiber capsule system and the uncinate fasciculus and have been associated with mapping sound to meaning, the acquisition of natural grammar, and syntactic processing. Dorsal pathways connect the left posterior temporal lobe with the left posterior frontal lobe via the arcuate fasciculus and the longitudinal fasciculus and have been associated with mapping sound onto articulatory based representations, processing complex syntactic operations possible due to an increase in syntactic working memory load, and may also serve higher level semantic and syntactic language functions (Friederici, 2011; Hickok and Poeppel, 2004, 2007; Saur et al., 2008; Weiller et al., 2009, 2011).

Although the left dorsal and ventral streams have mostly been discussed as separate systems, it has been suggested that the language-relevant brain areas can exchange information bidirectionally and in parallel via dorsal and ventral pathway systems and form a kind of feedback loop that needs to be passed at least once during language processing (Weiller et al., 2011).

Anatomical Asymmetries and Language Functions

To the naked eye, the left and right halves of the brain look very similar. Although the two hemispheres have a predominantly equivalent structure, anatomical (structural) asymmetries have been reported in various regions of the brain, and this not only in the adult but also in the immature human as well as in the ape brain (Hiscock and Kinsbourne, 2008). It should be noted that brain asymmetry is not necessarily a static feature and may vary in the general population. Empirical data suggest that experiential and environmental factors as well as behavioral and gender-related factors can modulate brain asymmetry (Renteria, 2012).

The important question, however, what these anatomical asymmetries mean at a functional level is not always clear. (Note that functional asymmetry is often referred to as lateralization).

The Planum Temporale

In 1968, Geschwind and Levitsky (1968) reported a leftward asymmetry of the planum temporale surface area (a region located in the superior temporal gyrus behind Heschl's gyrus). This and subsequent confirmation of these findings was interpreted by some researchers as neuroanatomical evidence for the left hemisphere's dominance for speech. Forty-five years later, the issue is still controversial. Opposing this view are observations that the incidence of left-hemisphere planum temporale asymmetry is around 60–80% while the incidence of left-hemisphere language lateralization has been estimated to be around 96% or higher (Dorsaint-Pierre et al., 2006). In addition, the measurement and boundaries to adjacent regions in individual studies differ and not all studies have reported asymmetries (Dorsaint-Pierre et al., 2006; Mazoyer and Tzourio-Mazoyer, 2004; Steinmetz, 1996). Considering the currently unclear situation, studies that link language dominance with anatomical differences in the planum temporale should thus be interpreted with caution until further evidence emerges.

The Auditory Cortex and Heschl's Gyrus

Another asymmetry in the auditory cortex concerns Heschl's gyrus whose volume is larger in the left than the right hemisphere. Although many individuals show this asymmetry, not all individuals do. This has been interpreted as suggesting that the relationship between structural asymmetry and language function in Heschl's gyrus is not always mandatory (Dorsaint-Pierre et al., 2006). Some research indicates that the anatomy and asymmetry of Heschl's gyrus in the auditory cortex may be a contributing predictor for learning foreign speech sounds. This is based on the observation that fast phonetic learners displayed a higher density of fiber tracts (white matter) in Heschl's gyrus than slow phonetic learners. At the same time, fast learners exhibited a leftward asymmetry in parietal lobe volumes while slow learners showed a more superior location of Heschl's gyrus (Golestani and Zatorre, 2004).

The Inferior Frontal Gyrus and Broca's Region

Anatomical differences between the two hemispheres have also been described in the inferior frontal gyrus, a brain region that in the left hemisphere entails Broca's area. These differences have been found at the cellular level, at the receptor level (important for signal transduction), and with fiber tracts (connecting brain regions). In the left hemisphere, these anatomical asymmetries have generally been interpreted as correlates for the lateralization of brain functions including language (Amunts, 2008; Amunts et al., 2010; Renteria, 2012). Already in 1980, Galaburda hypothesized (without brain imaging techniques) that the anatomical asymmetry of the pars opercularis, a region that is part of Broca's area, is a correlate of the functional lateralization of speech production (Galaburda, 1980 cited in Amunts et al., 2012). Others have speculated that the pars opercularis is use-dependent such that in the expression of speech, patients with left-hemisphere speech may employ more the left motor-related regions and patients with right-hemisphere speech the right motor-related regions (Dorsaint-Pierre et al., 2006). It has further been observed that the asymmetry in Broca's region (which is larger in the left hemisphere compared to its right-sided homologue) seems to increase with age with the parcs opercularis reaching adult levels around 11 years of age and the pars triangularis around 5 years of age. The observation that syntactic processes activate the pars opercularis and semantic processes activate the pars triangularis, and both processes develop at a different age in children has given rise to the *speculation* that the anatomically asymmetric development has a functional correlate (Amunts, 2008; Amunts et al., 2012).

Asymmetries in Pathological Populations

Abnormalities in asymmetries (including in the planum temporale) have also been found in certain pathologies such as developmental dyslexia, specific language impairment (SLI) and schizophrenia. Schizophrenia patients show reduced asymmetry in the volume of the left planum temporale, left Heschel's gyrus, and the right anterior cingulate gyrus (Crow, 2008; Honea et al., 2005; Kawasaki et al., 2008; Renteria, 2012). Auditory hallucinations in schizophrenia have been associated with increased blood flow in areas specialized for language. In SLI, abnormal asymmetry in Broca's area, atypical rightward asymmetry in anterior, and posterior peri-Sylvian areas (including the planum temporale) have been described and hypothesized to give rise to weak language skills (Badcock et al., 2012). Most neuroimaging studies have focused on relating patterns of activation in specific brain regions in response to specific tasks with regional anatomical deviances. Only recently have connectivity patterns between brain regions and the neurochemistry in these regions been investigated. It has, for example, been found that patients with autistic spectrum disorder – characterized by social, language, and other cognitive disorders – show an atypically connected brain as well as neurochemical abnormalities (Anagnostou and Taylor, 2011). Generally, however, the exact mechanism by which abnormal structural asymmetries in pathological populations may contribute to deviant language or communicative problems is still unknown and a matter of debate.

To sum up, several anatomical (structural) asymmetries of brain regions that belong to the language network have been described such as the planum temporale, Heschl's gyrus, and the inferior frontal gyrus including Broca's region. Abnormal asymmetries have also been described in certain pathologies such as developmental language disorders, schizophrenia, or autistic spectrum disorder. Although attempts have been made to relate such asymmetries to normal or abnormal language functions, it is currently not clear what exactly this relationship is.

Lateralization in Special Populations

The question whether special language skills implicate the two hemispheres in different ways has been a matter of wide interest, for example, in deaf people who use sign language or in people speaking two or more languages.

Sign-Language Users

The question what or how the two hemispheres contribute to language processing has most frequently been investigated with regard to spoken language with the vocal tract as the primary articulator. What, however, happens if the articulator consists of hands and nonmanual components (e.g., mouth) such as used by sign-language users? The first question that needs to be answered is whether the brains of deaf people look different from those who can hear. This question is currently underexplored but from the few studies that investigated this issue, it seems that landmark regions, such as the auditory cortex, seem to be similar in volume although there may be subtle differences in white matter connections (Campbell et al., 2008). At a functional level, the language regions in the left hemisphere seem just as important in deaf and hearing native signers as in spoken language users. This also pertains to impaired language processing: damage to the left hemisphere can produce aphasia in signers just as it does in spoken language users, whereas right hemisphere damage usually does not.

While most researchers agree that sign production is strongly left-lateralized, the contribution of the two hemispheres to sign perception is still controversial as findings do not always converge. For example, while some researchers report left-hemisphere dominance for signed language perception, others

have argued that the right hemisphere seems to be more recruited than the left hemisphere by native American sign-language users compared to written language processing of hearing nonsigners (Neville et al., 1998; for a summary see Campbell et al., 2008; MacSweeney et al., 2008). Explanations for these differences might be discrepancies in the experimental paradigms or differences between languages of the study participants.

Hemisphere differences have also been observed when information is conveyed by facial expression. For example, when British sign-language users use a headshake (or the manual equivalent) to signal negation, only the right hemisphere seems involved while emotional facial expressions can be processed bilaterally or predominantly in the left hemisphere. In hearing the emotional facial expressions of nonsigners are processed predominantly in the right hemisphere. This difference between sign language and spoken language users probably reflects that the face serves a wide range of functions in signers and, as a consequence, has resulted in cerebral reorganization (MacSweeney et al., 2008).

Multilingual Populations

The question where and how different languages are represented and processed in the brain of multilingual speakers has received considerable attention. Early studies investigated this question by electrically stimulating the exposed surface of the brain while multilingual patients underwent epilepsy surgery. The left hemisphere was involved in the representation of different languages when the brain was electrically stimulated during naming and reading tasks. The sites identified were widely distributed and overlapped only partially; there were sites at which one language alone was represented or sites at which both languages overlapped to different degrees (Ojemann and Whitaker, 1978; Rapport et al., 1983). Only two patients were reported that showed right-hemisphere involvement; one who generally showed right-hemisphere dominance for language and the other whose bilateral representation was probably due to a congenital lesion in the left-Sylvian fissure.

Subsequent neuroimaging studies using the fMRI or PET technique provided inconsistent results. Some early studies reported no interhemispheric difference for different languages (Klein et al., 1999), others reported representation of second languages in the left hemisphere alone (Kim et al., 1997) or in both hemispheres (Dehaene et al., 1997), or different findings for different participants (Chee et al., 2001). These inconsistencies are probably due to methodological issues such as different scanning techniques, different stimuli, tasks, task demands, and experimental procedures. Other reasons relate to different subject characteristics (age of acquisition, proficiency level, length of exposure to the second language).

Despite the inhomogeneity of studies, reviewing numerous neuroimaging studies targeting the neural bases for first and second language processing, Perani and Abutalebi (2005) concluded that a second language seems to be acquired through the same neural devices as a first language. Furthermore, tasks that engage specific aspects of linguistic processing activate similar brain patterns during first and second language processing. The authors further concluded that the most important variables that influence and modify the elicited brain patterns and the way a language is represented are language proficiency, age of acquisition, and the amount of exposure.

Differences in the linguistic structure of two languages have also been shown to influence language representation and processing in early and highly proficient bilinguals. Investigating syntactic processing in English and Spanish bilinguals, Kovelman et al. (2008) reported differentiated neural patterns of activation of the two languages and these differences were predictable from differences in the linguistic structures typical of the two languages.

Most neuroimaging studies report predominantly left hemisphere activation of both the first and the second language in the language-specific regions. These findings converge with behavioral studies that have shown similar left hemisphere dominant lateralization for the two languages in proficient bilinguals and stronger lateralization for the first than the second language in nonproficient (late) bilinguals (Hull and Vaid, 2007). Neuroimaging studies have not investigated language lateralization in young bilingual infants. Behavioral studies suggest that within bilinguals the two languages show functionally similar patterns in the sense that if one language in infant bilinguals is bilaterally organized so is the other, and when the first language of late bilinguals is left hemisphere dominant, so is the other (Hull and Vaid, 2007).

Lateralization in Pathological Populations

Structural asymmetries in pathological populations have already been discussed in Section Asymmetries in Pathological Populations. In the following, we will focus on the contribution of the hemispheres during the recovery process and how to determine language lateralization before surgery.

Hemispherectomy in Childhood

There are only few cases of children described in the literature whose entire hemisphere has been surgically removed (hemispherectomy) and the language tests in these children vary widely and are often limited to the word or sentence level. It is thus problematic to draw generalization from these individual cases. Nevertheless, the reported cases are witness to the extraordinary ability of the brain to recover and reorganize. Children born with left hemisphere pathology and subsequent left hemispherectomy may develop near-normal speech and communication abilities. The situation seems different for children who develop pathology after 5 years of age. In these children, after left hemispherectomy, receptive language functions were often spared while productive language functions recovered slowly and incomplete (summary in Stemmer, 2006). In the right hemisphere, a variable pattern of language networks activated in the inferior frontal regions when words had to be generated, while a more consistent pattern was observed in temporal and precentral regions (Liégeois et al., 2008).

For a long time, it was believed that this recovery potential is limited to children and does not apply to adults. Undoubtedly, recovery and reorganization in children can be very dramatic but it also occurs in adulthood, even until late in life, albeit to a lesser degree.

Aphasia

Aphasia is a loss or impairment of the ability to appropriately produce and/or comprehend language, usually due to left-sided brain damage such as a stroke. Clinical recovery from aphasic syndromes in adults can be observed over days, weeks, months, or years after the incident.

Acute Phase after Brain Damage

Neuroimaging studies have tried to elucidate the neural mechanisms underlying early recovery. In the early acute phase (up to about 6 months) after a stroke, recovery of language function depends on how well blood supply returns to the tissue that has (at least partially) been preserved. This is called reperfusion. It further depends on how well edema (abnormal accumulation of fluid) at the lesion site are resolved and how well the metabolism at implicated but distant sites of the infarct is restored (Hillis et al., 2008; Lee and Hillis, 2008; for a summary see Berthier et al., 2011). Empirical data suggest that in acute aphasia after a stroke the main mechanism underlying recovery is the restoration of brain networks around the damaged site in the left hemisphere. Although contribution of the right hemisphere does occur, it is frequently minor unless the left hemisphere language networks are severely damaged (Heiss and Thiel, 2006). The more efficient the left hemisphere networks, the less the contribution of the right hemisphere (Winhuisen et al., 2005, 2007).

Chronic Phase after Brain Damage

Contrary to early beliefs that there is no language recovery the first year after the incident, we now know that significant improvement of language functions can still occur for many years later. Unlike the acute phase, the main mechanisms that drive recovery in the chronic phase seem to be the recruitment of additional brain areas (compensation) and displacement of a primary language area (reorganization) (for a summary see (Berthier et al., 2011; Meinzer et al., 2008, 2011)). The reorganization of neural networks can be triggered spontaneously or through intensive training, pharmacological treatments, or electromagnetic stimulation (repetitive TMS; transcranial direct current stimulation). Both hemispheres seem to be involved in the reorganization of brain networks in chronic poststroke aphasia but due to individual variability and the heterogeneity of the patient population and lesion characteristics, it has been difficult to specify the role that each hemisphere occupies in this process (for details see Berthier et al., 2011).

Defining Hemispheric Lateralization in Presurgical Patients

When patients need to undergo neurosurgical intervention, for example, to resect epilepsy foci or a tumor, one tries to preserve neural substrate that is essential for important functions such as aspects of language. For a long time, the gold standard to determine in which hemisphere language is lateralized in these patients was the presurgical Wada procedure. During this procedure, one hemisphere is anesthetized while the patient has to perform simple language tasks such as naming objects or following simple commands. If the left hemisphere is anesthetized and the patient is unable to perform the language task, this suggests left-sided dominance for the task. Most neurosurgical patients tested with the Wada procedure have been shown to be left hemisphere dominant. Right-hemisphere dominance for language in neurosurgical patients has been estimated to range from 2 to 10% (for a summary see Drane et al., 2012).

Comparisons between the rather invasive and thus limited Wada test and the noninvasive fMRI procedure has shown that there is a good agreement between the two procedures. The fMRI procedure may even outperform the Wada procedures due to its less limiting time constraints and more flexible application (Binder, 2011; Dym et al., 2011). In addition, rather than a 'pass or fail' judgment, fMRI may improve prediction accuracy (such as the risk for postoperative naming deficits) when combined with other noninvasive measures and more realistically predict the actual outcomes (Binder, 2011).

Lateralization in Males and Females

A popular belief is that language functions are more lateralized to the left side of the brain in men and represented more bilaterally in women. Unfortunately, scientific support for this statement is ambiguous. Although a number of brain imaging studies have reported more bilateral activity during language processing in women compared to men, meta-analyses of these studies did not find a significant difference of language lateralization in men or women, regardless of whether they were adults or children (for a summary see Wallentin, 2009). Aside from methodological differences and high-individual variation, many studies that report differences relied on a relatively small sample size while studies that did not find differences were based on larger samples. Studies investigating low-level processing (verb generation, word completion, or semantic word judgment tasks) reported no lateralization differences in men or women while others using rhyming judgments or passive listening to spoken narratives found more bilateral activation in women compared to men (for a summary see Stemmer, 2006).

Gender differences at the structural level have also been documented. In males, the left planum temporale is larger than its right homologue, whereas women do not show this difference. Whether the corpus callosum (CCA), a large fiber bundle that connects the two hemispheres, is larger in females than in males has been controversial. While some researchers conclude that the sex-related CCA difference is a myth (e.g., Wallentin, 2009), Ardekani et al. (2012) measured the cross-sectional area of the CCA and reported a larger CCA in females compared to males. Regardless of the controversies surrounding structural brain asymmetries in males and females, an important point is that it is currently not clear what such differences mean in terms of their functional significance such as language lateralization.

Genetics and Lateralization

Some developmental language disorders such as dyslexia or SLI have been associated with genetic abnormalities (Ramus and

Fisher, 2009; Newbury et al., 2010). It is further assumed that genes are involved in determining cerebral asymmetry (Bishop, 2013). The question thus asked is whether there is a link between the genetic underpinnings of developmental language disorders and cerebral asymmetry.

Neuroimaging studies have shown anatomical (structural) asymmetries (see Section Asymmetries in Pathological Populations) as well as a poorly functionally lateralized brain such as reduced left hemisphere activity during word generation tasks in developmental language disorders. Several scenarios have been suggested that may link genetic influence, asymmetry, and language problems. One scenario is that genes influence language disorders by affecting cerebral lateralization. Another scenario suggests that the same genes that affect language disorders also affect lateralization. Finally, genes influence language disorders and the disorder results in weak laterality. (See **Figure 4**; for details see Bishop, 2013.) Research on linking the genetics of language disorders with the genetics of cerebral lateralization is still in its infancy and it is currently not possible to draw well-founded conclusions. Although genetic abnormalities have been found in some developmental language disorders and genes are most probably involved in determining cerebral asymmetry, the role of these genes, their interaction with, and the influence of nongenetic factors on cerebral asymmetry is currently open.

Lateralization across a Life Span

An old question that has attracted much research is whether there are any age-related changes in language lateralization. Despite the large corpus of data accumulated, the evidence is often difficult to interpret and ambiguous. The main models that have been advanced in relation to whether language lateralization changes across the life span are the developmental invariance model, the progressive lateralization models, and the progressive degeneration model (for a summary see Hiscock and Kinsbourne, 2008). The developmental invariance model posits that the left hemisphere is specialized for language at the time of or even prior to birth and no changes will occur during further development. The progressive lateralization models postulate that the bilateral (functional) symmetry of the infant's brain gradually lateralizes to the left hemisphere at some stage

Figure 4 Four path diagrams of the association between weak cerebral lateralization for language and language and literacy problems. These causal models are simplified abstractions and not mutually exclusive, but they illustrate the differing predictions about the pattern of associations that might be found between genotypes, language and literacy impairment, and cerebral lateralization. The endophenotype model depicts the situation in which genes that influence risk for language impairment do so by affecting cerebral lateralization. This model predicts that cerebral lateralization should be at least as heritable as language impairment, with the same genes affecting both traits. The pleiotropy model similarly assumes that the same genes that lead to risk for language impairment also affect cerebral lateralization, but there is no direct causal link: Weak laterality and language impairment co-occur because they have common origins, not because one causes the other. In the additive/interactive risks model, the genetic risk factors for language impairment do not affect lateralization. However, weak laterality, which could have genetic and/or nongenetic origins, exerts an independent causal influence on language impairment, which may add or interact with other genetic risk factors. In the neuroplasticity model, cerebral lateralization has no causal effect on language; rather, language impairment influences how the brain develops and is associated with weaker cerebral lateralization. The dotted arrows indicate that, for each construct, there will be sources of variation in addition to those depicted in the model. Bishop, D.V., 2013. Cerebral asymmetry and language development: cause, correlate, or consequence? Science 340, 1230531.

during development (e.g., around puberty or by 5 years of age), or during maturity, or even into senescence. The progressive degeneration model suggests that the function of one hemisphere (usually the right) degenerates more rapidly than the function of the other thus leading to an asymmetry. While most evidence seems to speak against the developmental invariance model, general problems, such as insufficient data on functional maturation in relation to asymmetry or methodological limitations with very young or very old populations, make it difficult to obtain a clear picture.

Latin-American Legal Systems

Javier Couso, Facultad de Derecho, Universidad Diego Portales, Santiago, Chile

Abstract

'Latin-American legal systems' is a label that groups together a diverse set of 20 countries that share a common historical background, geographical proximity, similar cultural traits, and, often, an important degree of economic interaction. As a consequence of these features, they generally exhibit similar patterns in their law. They also differ in important ways, however, such as regarding the degree to which formal state law penetrates social, economic, and political life; the different roles played by constitutions and judicial systems; and the extent to which they exhibit legal pluralism. After accounting for similarities and differences among the Latin-American legal systems, the article describes the role that International Human Rights Law is playing in the legal life of the region, as well as the convergence with Anglo-American legal tradition, in both Public and Private Law.

I

The expression 'Latin-American legal systems' is an intellectual construct designed to group together a diverse set of countries that share a common historical background, geographical proximity, similar cultural traits, and – often – an important degree of economic interaction. As a consequence of these features, they generally exhibit similar patterns in their law.

Historically, the 20 Latin-American states (Argentina, Brazil, Bolivia, Chile, Colombia, Costa Rica, Cuba, Ecuador, El Salvador, Guatemala, Haiti, Honduras, Mexico, Nicaragua, Panama, Paraguay, Peru, Dominican Republic, Uruguay, and Venezuela) were classified as belonging to the 'Civil Law Tradition' (Merryman, 1969), given the influence that Continental European Law had in the region since the colonial era and throughout the formative years as independent nations – in the first half of the nineteenth century – particularly in the domains of Civil and Procedural Law. As members of this legal tradition, most of the Latin-American countries exhibited a strong attachment to codified law and a corresponding opposition to judge-made law and to the doctrine of 'stare decisis.' Also in line with the Continental European tradition, the systems of this region gave a prominent role to legal academics in the development of law, through the elaboration of doctrine. Further characteristics of the Latin-American legal systems include the sway that legal formalism had over judges in their adjudicative role, and the hierarchical structure of the judiciary. Finally, many observers emphasize the chronic inability of most of the formal legal systems of the region to actually govern the social, political, and economic relations of their countries (García Villegas, 2009; Nino, 1992). Indeed, ever since the colonial practice of formally recognizing the legitimacy of royal decrees but then openly disobeying them ('*La ley se acata, pero no se cumple*'), the incapacity of formal state law to penetrate society has been a constant concern in many Latin-American countries.

Although the assessment that the Latin-American legal systems are the childbirth of Continental European Law is largely right when it comes to Private Law, this is not the case with regard to Public Law, where the United States' constitutional model had an enormous impact (Gargarella, 2013). This influence explains why all states of the region have presidentialist regimes and why several of them have a federalist system (Brazil, Mexico, and Argentina). Thus, the notion that Latin-American legal systems are simply a subset of the 'Civil Law Tradition' has to be qualified, and attributed to the fact that, until recently, legal analysts of the region focused mostly on Private Law.

II

In spite of the common traits exhibited by the legal systems of Latin America, it has to be noted that there are significant differences in terms of the relevance of formal state law in each of the countries of the region (Sieder, 2002). This is intimately related to the degree of state formation exhibited by the Latin-American nations (López-Alves, 2000). Thus, while some countries have managed to consolidate constitutional regimes where state law reaches most of the national territory (Argentina, Chile, Costa Rica, and Uruguay), others exhibit weak states, where the formal legal system is unable to reach vast segments of society. These places are instead ruled by informal practices (Haiti and Paraguay) or, in some cases, by indigenous law (Bolivia, Guatemala, and, to a lesser extent, Ecuador and Peru). The rest of the states of the region fall in between the poles of the prevalence of state law or the coexistence of the latter with indigenous and other types of informal law.

An additional difference that can be observed among Latin-American states is the degree of consolidation of the rule of law – and, more specifically, judicial independence – exhibited by each of the countries of the region. Thus, for example, a report by the 'World Economic Forum' ranks Chile, Costa Rica, and Uruguay within the top 30 states in the world in terms of judicial independence, while it found Paraguay and Venezuela to be the countries with the least independent judiciaries of the 139 nations surveyed (*Global Competitiveness Report 2010–2011*). These rankings suggest a disparate reality within the region when it comes to judicial autonomy from the government; in some countries the judiciary is able to do its work with a reasonable degree of autonomy from the executive branch, but in others the judiciary is completely dominated by the executive.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86136-X

Something similar happens with the degree of corruption exhibited by the different countries of the region – a proxy for adherence to legality by political authorities – as reported by the organization 'Transparency International.' According to this organization's *Annual Report 2012*, Latin-American states are distributed within a wide range in terms of perceived corruption, with Uruguay and Chile ranking among the 20 most transparent states while Venezuela and Haiti rank among the 10 most corrupt.

The indicators just mentioned suggest that the gap between 'law in the books' and 'law in action' also varies widely in Latin America. The same goes for the prevalence of legal pluralism. Concerning the latter, and given the fact that there is quite some variation in the percentage of indigenous peoples living in the different Latin-American states (from over 50% of the population in Bolivia, to less than 1% of the population in Uruguay), it is not surprising that the degree to which indigenous law coexists with formal state law also varies immensely. In Bolivia, Guatemala, and Ecuador, for example, the role of indigenous law is extremely important, while in Uruguay, Costa Rica, and Chile it is more limited.

III

In the previous sections we have seen that – in their formative years – most Latin-American countries embraced codification as a key feature of their state-building efforts. The goal was to affirm national identity, as well as to introduce clarity and coherence to Private Law (Mirow, 2004). This was seen as a necessary step to enhance commercial transactions and to better regulate family relations, given the chaotic mass of colonial law, local regulations, and informal practices prevalent at the time of independence from imperial rule. The codification of Civil Law – which was done in most countries of the region during the last decades of the nineteenth century – was followed by the introduction of codes of Civil Procedure, codes organizing the judicial branch, and codes of Criminal Law and Criminal Procedure.

In the case of Public Law, the adoption of written constitutions was done much earlier, that is to say, soon after independence from imperial rule. As stated above, the model for most of the region's Constitutional Law was the United States, given that it was the only nonmonarchical country in existence at the time. Having said this, the chronic political instability experienced by most Latin-American states at the time meant that existing constitutions were constantly replaced by new ones – or were profoundly amended – as a result of revolutions, civil wars and other types of generalized violence. This explains the astonishing number of constitutions that Latin America has had over the last two centuries (Elkins et al., 2009). The high number of constitutions has not, however, always translated into limited government, due to the heavy use of 'states of emergence' throughout the region's history (Loveman, 1993). Even though the chronic reality of a proliferation of formal constitutional charters and a lack of substantial constitutional rule of law just noted was the norm during the nineteenth century, a few countries eventually managed to establish relatively stable and meaningful constitutional regimes (such as Chile and Argentina, at the turn of the century).

Observers of Latin-American Public Law attribute many nations' difficulties in consolidating stable and effective constitutional regimes to a number of factors, such as geographic and ethnic fragmentation, a profoundly unequal social structure and the lack of a 'culture of rights' (Rosenn, 1990; Schor, 2006). Others argue that the root cause of the lack of a strong constitutional culture in the region is the persistence of a long colonial legacy characterized by a centralized, authoritarian, and hierarchical exercise of political authority (Adelman, 1999).

In spite of the problems just noted, toward the middle of the twentieth century a sizable number of states in the region managed to consolidate constitutional regimes that were gradually introducing a democratic rule (this was the case in Argentina, Brazil, Chile, Colombia, Peru, Venezuela, and Uruguay). Parallel to this process it should be noted that, starting with the Mexican Constitution of 1917, many countries of the region adopted what is known as 'social constitutionalism,' that is to say, they introduced into their constitutional charters various social rights, such as the right to work, education, health care, housing, and so on.

In the decades after World War II, the trend toward the inclusion of new rights continued, as many Latin-American states ratified a large set of both universal and regional human rights treaties; these would later exert an important influence in domestic constitutional law (Franklin, 2008). The introduction (in the 1970s) of a regional system for the protection of fundamental rights, the Inter-American Human Rights Court and Commission, represented a crucial development in the Latin-American legal systems, since it provided a regional arena where individuals can seek judicial remedies when their own states have violated their human rights and the domestic courts have failed to protect them (Shaver, 2010).

Even a brief account of the Latin-American legal systems has to provide an account of the emergence – during the first decade of the current century – of what has been labeled 'radical constitutionalism.' This emerged in the so-called 'Bolivarian republics' of Venezuela, Bolivia, and Ecuador, as a result of popular frustration with the inability of the previous constitutional regimes to make decisive progress toward reducing poverty and inequality, as well as their negligence in controlling corruption (Couso, 2014). The lack of legitimacy of liberal constitutionalism in the above-mentioned countries was seized upon by a group of highly charismatic leaders (Hugo Chavez, in Venezuela; Evo Morales, in Bolivia; and Rafael Correa, in Ecuador) who, after gaining control of the executive and legislative branches, initiated an aggressive program of constitutional reform explicitly aimed at the political and social 'rebirth' of their respective nations. Given that the constitutional charters in place at the time did not contemplate referendums to ask the people about the need to adopt a new constitutional order, they used executive decrees calling for these referendums to call for constitutional assemblies that eventually passed new fundamental charters. These radical constitutional experiences purposefully weakened the principle of separation of powers (especially to the detriment of the autonomy of the judiciary); expanded the power of the executive branch; and – in the case of Venezuela and Ecuador – substituted bicameralism for unicameralism in the legislative branch, all transformations based on the notion that a 'unity' of

powers was needed to deliver radical social change (Viciano and Martínez Dalmau, 2010). The actual impact of this type of radical constitutionalism is yet to be seen, but in the view of some observers it has already done much to weaken the rule of law in the 'Bolivarian republics.'

IV

The adoption by most countries of the region of (an ever expanding) International Human Rights Law, as well as the Inter-American Human Rights system, have been important sources of transformation of the very conception of law in the region, leading to the weakening of the legal formalism characteristic of Latin-American legal systems and the development of a more 'justice-oriented' conception of law. Indeed, as López Medina (2004) has suggested, the processes noted above, coupled with the influence of a human rights–based understanding of law typical of postwar Continental European legal doctrine (Shapiro and Stone Sweet, 2002) have led to the increasing abandonment by Latin-American legal actors of the legal positivism advocated by Hans Kelsen that was so dominant in this region for most of the twentieth century. This change in the conception of law and legality has also provoked a change in the understanding of the role of the courts, from one in which they were largely deferent to legislative sovereignty, to one which openly embraces the judicial review of the constitutionality of legislation, a doctrine which has in turn led to growing degrees of judicialization of politics (Couso et al., 2010; Sieder et al., 2005).

The developments mentioned above have profoundly transformed the role played by the courts in many of the legal systems of Latin America (particularly in Colombia, Costa Rica, Argentina, and, to a lesser extent, in Brazil, Mexico, Chile, and Peru), a process which in turn has changed the expectations of legal academics, lawyers, and regular citizens about the role that law and courts should play in the social, political, and economic life of their nations. Another consequence of the increasing power of Latin-American courts and, in particular, of the incipient development of judge-made law has been the introduction in some countries of mild forms of *stare decisis* (the doctrine of precedent), something that suggests a degree of convergence with the Common Law tradition.

The convergence just noted has also been facilitated by the large number of legal academics and practicing lawyers who – starting in the 1970s – have received graduate legal education in the United States, the United Kingdom, and other former British colonies. Thus, after a century in which Latin-American legal scholars and practitioners almost exclusively attended Continental European Law schools for postgraduate legal education (French and Italian ones, for legal training in Private Law; German ones, for legal training in Criminal Law), in the last decades of the twentieth century growing numbers of them started to attend LL.M.s and S.J.D.s in Anglo-American institutions (Dezalay and Garth, 2002).

V

The legal actors of the Latin-American legal systems have changed significantly over the last decades, due in part to the developments described in the preceding section. The most relevant transformation in this domain is the growing centrality of judges vis-à-vis legal academics, a process that would have been unthinkable earlier in Latin America's legal history, where the latter dominated the articulation of a legal discourse then invoked by practitioners and judges. Of course, given the significant variations already noted among the different countries of the region, the degree to which judges have become key actors in the development of law and legal doctrine through their decisions varies widely. Thus, for example, in Argentina and Colombia this trend is most noticeable, while in Uruguay and Peru legal academics continue to overshadow judges.

The growing relevance of judges in Latin America is also the result of large programs of judicial reform backed by the World Bank and other international organizations, within the context of transitions to democracy and economic globalization. These programs, which introduced in many Latin-American countries 'councils of the magistracy,' have not, however, always been successful (Prillaman, 2000).

Another area of the Latin-American legal field where one can observe significant change is in legal education, which has become more diversified, professionalized, and globalized in many states of the region (Pérez-Perdomo and Gómez, 2008). Indeed, as opposed to the classical legal education performed by successful legal practitioners who would teach for a few hours a week using the traditional model of formal lectures based on a close exegesis of codified law and a few treatises, a number of Latin-American countries have managed to introduce a truly professional legal education, with specialized law professors fully dedicated to teaching and researching (this is particularly the case in Colombia, Chile, Brazil, Mexico, and Argentina). Although it is still too soon to assess the impact that this dramatic change in legal education will have in the said countries, there is already evidence that the trend throughout the region is toward this professionalized model.

Related to changes in legal education is the introduction in recent decades of programs for the training of judges, both as a requisite for admission to judgeship and for the judges' continuing education. One important example at hand is Chile's Judicial Academy, introduced in the 1990s (Skaar, 2010), and based on the French model.

VI

As this article shows, Latin-American legal systems exhibit some common features but also have important differences. The similarities are the result of three centuries of common imperial history that left an important legacy in the social, political, and legal structures of the countries of the region, as well as in their cultures. The differences are the result of the distinct political, economic, and constitutional paths followed by each of the 20 Latin-American states over the last two centuries.

Furthermore, it is important to highlight the convergence with Anglo-American law that in recent decades can be detected in almost all Latin-American legal systems, due to both economic and legal globalization (Friedman and Pérez-Perdomo, 2003). This convergence is now apparent in both Public and Private Law. In the case of the former, it is expressed

in the fact that many Latin-American constitutional and High Courts often cite decisions by the United States' Supreme Court, while in the case of the latter, it is expressed by the adoption of contract, tort, and family law doctrines and judicial decisions developed in the Anglo-American legal world. Finally, convergence has been heavily driven by the growing importance of International Human Rights Law in most Latin-American legal systems.

Abstract

Beginning by presenting his 2005 book *Reassembling the Social* as a key text for social scientists, this article introduces Latour's social material philosophy and exploration of a reality consisting of actants, networks, and lively relationships. It puts the metaphysical Latour side-by-side with the one interested in questions of environment, politics, and practical methods. It aims to pull diverse elements of Latour's writings and associations together into a useful summary, while remaining faithful to his theoretical commitments to heterogeneity, translation, mutation, and hybridity.

Introduction: Bruno Latour Reassembles the Social

There is something slightly uncomfortable about summarizing the work of Bruno Latour for an encyclopedia of the social sciences. Latour suggests in his book *Reassembling the Social* (2005) that there are only 'two drawbacks' to be found in the idea of a 'science of the social': 'the word 'social,' and the word 'science' (2005: 2). This combative relationship with the disciplines closest to home for a supposed sociologist and anthropologist is an integral part of Latour's project. He seeks a new route out of the contradictions and epistemological impasses of modern thought, especially its desire to separate out purified entities instead of engaging directly with hybridity and connectedness. One part of this project has involved taking apart the idea of a homogeneous and authoritative science with special access to the real world. He shows instead how sciences in the plural are grounded, situated practices that build up their claims out of multiple relationships with different kinds of materials and methods. Another part of his project, more unsettling for social scientists, challenges the notion that society is a distinctive entity, separate from nature and from technological artifacts. Instead, Latour leaves us with a motley collective of humans and nonhumans, of social, technological, and natural issues all mixed up together, and he offers us the instruction that we must learn anew, every time, the specific and contingent ways in which entities associate together.

For some in the human and social sciences, especially in the multidisciplinary field of science studies, Latour's provocative approach has been invigorating and transformative. His work has also been taken up by philosophers trying to move beyond some of the dead ends of postmodernism/post-structuralism and toward frameworks foregrounding lively materialities (Bennett, 2010; Harman, 2009). Within the mainstream of the social sciences, however, Latour's work has often been met with indifference and sometimes hostility. This is a loss, I think, especially to social theory. His work goes to the very heart of what we mean when we talk about society, and it stimulates us to think in new ways about the most fundamental logics and dynamics of social action. He gives us a rigorous alternative to the structure–agency dyad and asks us to question how much we cling, often despite ourselves, to some version of a society *sui generis* to ground social inquiries. He gives us ways of exploring social stability and social change in terms of contingent, constructed networks, and ways of rethinking social action to include lively nonhuman actors. As well as trying faithfully to describe the hybrid worlds we inhabit, he has developed hopeful and robustly realistic proposals about how we can find better ways of living in and with them. Latour has a lot to offer social science, even if he does not like the label.

I begin here with *Reassembling The Social* because it speaks most directly of all Latour's writing to and about social scientists. It is not always a comfortable conversation, but it is an important one. It asks us to reimagine the stuff of our subject matter in terms of diverse and open-ended associations between human, technological, and natural entities, across which the lively capacity for action and the objective capacity to endure are distributed in surprising ways. *Reassembling* offers social scientists a way in to Latour's wider project, which as we will see is simultaneously ontological, methodological, and political. Across his extensive writings he weaves and reweaves some core propositions. There is the refusal of binary categories (nature/society, objective/subjective, facts/values) in favor of a rich picture of hybrids, networks, and relations. There is the insistence that nothing can be reduced to anything else. There is a rejection of the idea that some important things (identities, actions, ideas) are 'socially constructed' while other important things (objects, physical forces, nature) are external and separate from us. *Reassembling* very clearly links these ontological themes back to questions of methods and how we find out about the modes of association that make up the messy worlds we inhabit.

Who Is Latour?

Two recent full-length studies take different approaches to Latour's plural intellectual stances and unusual academic biography (Blok and Jensen, 2011; Harman, 2009). Neither fully resolves the question of his disciplinary identity and I do not propose to do so here. Instead, I start with an overview of his current professional affiliation and projects and then work backward to indicate some of the contexts, alliances, collaborations, and institutions through which he has forged his ideas.

Latour is currently Professor and director of the Theory of Actor-network and Research in Digital Environments (TARDE) program at Sciences Po (Institut d'études Politiques de Paris) in Paris, where he founded the médialab research center for digital

social sciences and is director of the innovative interdisciplinary Experimentation in Arts and Politics (SPEAP) program. Both ventures speak to his growing interests in the intersections between disciplines and the connections between different forms of inquiry. In 2010, he was awarded a European Research Council Grant to pursue new work on an 'anthropology of the moderns'. This has recently appeared in the form of a book, *An Inquiry into Modes of Existence* (2013), and a collaborative Web site (AIME). They explore (and invite collaborators to explore) the plurality of worlds or realities that in different ways organize how we live, what we know, and who we are. In law, religion, science and aesthetics we can discover different sets of conditions for deciding on what is true and false, good and bad, what matters and what is unimportant. These are conditions that can only be seen in all their strangeness if we accept that we were never really modern, that is, that there was never a stable objective world out there and that human agency alone does not make history. The book develops concerns that were present in some of Latour's earliest writing (*Irreductions*, available in English in print as an appendix to Latour (1988); see Tresch (2013) and Harman (2009)), and revitalizes the philosophical and theological studies he pursued as an undergraduate at the University of Bourgogne in Dijon and later at Tours, where he received his doctorate in 1975.

In 2013, Latour won the Holbert Prize for outstanding scholarly work in the humanities and social sciences. Here he was identified as a sociologist and anthropologist, linking him back to the disciplinary affiliations of the earlier parts of his career. Between 1982 and 2006, Latour was based at the Centre de Sociologie de l'Innovation at the Ecole Nationale Supérieure des Mines, Paris. During this period, he published some of his best known books, including his intervention in the philosophy of modernity, *We Have Never Been Modern* (1993); his reflections on science studies, the 'science wars' and the limits of social constructionism, *Pandora's Hope* (1999); his argument for a sociology of associations, *Reassembling the Social* (2005); and his proposal for new political institutions fit to deal with nature and environmental crisis, *Politics of Nature* (2004). With Callon, Law, and others he developed under the eventual rubric of actor-network-theory (ANT) some new approaches to explaining how scientific and technical things are made and circulated. Against the grain of dominant models in the philosophy of science, Latour argued that scientific claims, like technical objects, are not discovered but rather practically and painstakingly constructed. Once a fact or a technological object starts to hold together, its path to legitimacy and acceptance is not about people recognizing its necessary or self-evident truth. Rather it is about making the fact or object more widely relevant or useful by extending the contexts in which it is relevant or the network within which it makes sense.

These arguments emerged from Latour's work in the field of sociology of science, starting with his first published book, *Laboratory Life* (Latour and Woolgar, 1986). Its findings were rooted in an ethnographic study of Roger Guillemin's neuroendocrinology laboratory group at the Salk Institute for the Biological Sciences in La Jolla, California, where Latour spent two postdoctoral years (1975–77). *Laboratory Life* sends back reports from the everyday life of scientists. It explains the enormous effort and the great diversity of actors (texts, machines, and biological things, as well as scientists) that are needed to translate material substances into written traces, and thereby to stake a scientific claim to have discovered the truth about a bit of the physical world. In his later work, *Science in Action* (1987), Latour clarifies his agonistic model of the construction of scientific facts, that is, the combative and contesting nature of scientific practice. He also shows how expensive it is, in terms of both money and effort, to contest and challenge a scientific claim once it has traveled widely, been stripped of its 'modalities' or contingencies, and been reduced by usage simply to its inputs and outputs.

Latour often claims to be working on a 'practical metaphysics' (2005: 50). His varied academic biography shows how this claim is rooted in a career made up of different disciplinary orientations, multiple empirical encounters, and diverse methods of inquiry. He has been a laboratory ethnographer, peering over the shoulders of endocrinologists, and a philosopher of knowledge, making general claims about the nonexistence of external reality. He has been the historian of a modernity he claims did not happen, and an analyst of the future institutions that might help to usher in a new politics of nature. He has studied Biblical exegesis and worked in international development in Cote d'Ivoire (during civilian national service in the 1970s; see Tresch, 2013; Harman, 2009). Across all these engagements, he now says, he "never had any other interest than the exploration of the many ways there are to find the truth of a situation" (Holberg, 2013).

Metaphysics and Methods: from Culture and Nature to ANT and Ants

The multiplicity of truth. As the quote above might suggest, the Latour currently taking center stage is primarily located in relation to metaphysical issues, that is, questions of "the basic structure of the world" (Latour, 2005: 51). In an article prefacing his most recent book, Latour narrated his "coming out" as a philosopher (2010). In 2009, Harman's *Prince of Networks* (2009) read Latour as a neglected metaphysicist. Latour wears the mantle well. His work pokes from different directions at how humans and their technologies manage to produce workable truths about the fundamental nature of existence. Metaphysics has something to do with what seems to exceed, transcend, or precede the physical, and hence becomes deeply troublesome and deeply interesting after the emergence of modern science, issues that Latour explored since *We Have Never Been Modern* (1993). And if metaphysics now sometimes seems to be a leftover category for aspects of philosophy that do not fit neatly into the boxes of ethics, epistemology, aesthetics or logic (Van Inwagen, 2013: pt 4), then perhaps it is a good home for Latour's commitment to thinking with and about hybrids, quasi-objects, collectives, and heterogeneous cosmologies.

To start with the metaphysical Latour is to start with his arguments about what the world is like. It is to encounter a vivid ontology in which all things are thoroughly lively and relational. Latour's ontology is best apprehended as a kind of monism (Bennett, 2010) which attempts to understand reality in terms of a single flat plane rather than starting with distinctions between types of things. It is especially hostile to binaries and dualisms. In Latour's cosmology there is no nature

separate from culture. Society is not an object *sui generis*. The capacity for autonomous agency is not restricted to humans or compared to objective things and forces. Instead we find a plurality of concrete, irreducible entities, or 'actants.' Actants are constituted through their connections. Individual people *are* networks, made up of material substances and physical processes; of thoughts and self-awareness; of the things we take into ourselves and the arrangements and others outside us who make us what we are. People *make* alliances too, by persuading others, both human and nonhuman, to lend their interests to building and stabilizing a set of connections that can achieve something new or make something happen: in the language of actor-networks, through acts of enrollment or translation.

All entities, human and nonhuman, are lively and agential if they have the capacity to affect and effect other things. Events and identities are not reducible to single causes or determinants, but are contingent outcomes of an assembly of forces and connections, more or less temporary congealings or stabilizations of diverse and dynamic forces. If things seem to run on familiar tracks, if objects, institutions, and actors appear durable and stable, then the networks are bedded down and largely invisible. This does not mean, however, that the things we treat as real and reliable in our world do not depend on ongoing work to maintain them. If they are to matter, to remain stable and effective and meaningful, all networks involve work – that is, active doing, commitment, activity, and effort. Latour then proposes a kind of relational realism in which connection is the substance of the world. It is also a dynamic kind of realism. In order to be and to matter, things have to be practiced or performed. For Latour, "an actant is always an event" (Harman, 2009: 17). The more connected a thing is and the more work that goes into making it up, the more constructed it is. And the more connected and well-constructed a thing is, the more real and robust it is (Latour, 2005). Here we find some of the most interesting and also the most contentious elements of Latour's thinking. Reality is not the opposite but rather the outcome of construction and relatedness. This approach challenges the assumptions of (scientific) realism as well as rejecting the implications of (social) constructionism. As a result it has been the object of ferocious critique from both sides (Latour, 1999).

Both approaches are wrong, Latour argues, because of a fundamental historical misstep – the emergence of the self-conscious moderns and their powerful but deluded model for understanding the world. In *We Have Never Been Modern* (1993), Latour explains that the 'modern Constitution' involves two opposing dynamics. A rigorous conceptual process of purification divides the world into separate realms of nature and culture, divides thought into contrasting epistemologies relating to either objective facts or subjective meanings, divides things and materiality from beings and agency. But the very impetus of modernity is to mix things up. Processes of hybridization and the making of imbroglios are the practical lifeblood of the moderns. From the backroom experiments of the earliest natural philosophers to the most elaborate industrial enterprises, from the discovery of oxygen to the manufacture of automobiles, our social life constantly articulates human interests, technological apparatus, natural resources, and practical know-how. Purification, according to Latour, is a smoke screen. By refusing to recognize its own monsters and mixtures, modernity in fact allows them to be produced. But if modernity rested on the apparent human capacity to stand apart from and objectively know nature, then it never really was. We have never been modern.

Here we see very clearly the metaphysical Latour and can begin to understand why this work has been important and innovative. But this metaphysical Latour, however interesting, perhaps threatens to overshadow equally compelling aspects of his work. Firstly, there is the ecological Latour who has engaged since *Pandora's Hope* in 1999 with how we nonmoderns can more honestly describe the hybrid techno-collectives we have made, revise our methods for living with environmental imbroglios, and devise a 'parliament of things' for managing the natural-social collective (Latour, 1999; see Chapter 6). *Politics of Nature* (2004) takes up these questions with gusto, developing a new focus on ecological philosophy and politics that continues to drive much of Latour's work (2013). Here he argues that environmentalism took a wrong turn when it tried to save nature or bring it into politics. Both moves simply reiterate a division between human values and natural objects that does not exist. Environmental crisis, Latour tells us, is a way of noting that many lively hybrid objects are insisting on recognition, and we cannot answer to them from within a modern constitution that keeps facts and values separate. The book goes on to describe the logics of a new constitution and new skills that could help us to better recognize and manage all the elements of our cosmos. Here Latour outlines a cosmopolitics (the term comes from the philosopher Isabelle Stengers; see Stengers 2010) that is unabashed in its desire to find better ways of living with the worlds we create.

Secondly, the metaphysical Latour threatens to overshadow the Latour of methods. This Latour emerges in the work on science studies with the lab ethnographer watching bioscientists at work in *Laboratory Life*. This methodological focus is developed in *Science in Action*, which formalizes 'rules of method' (1987: 258–259) to help interested analysts learn to 'follow scientists and engineers around,' watch 'science in the making,' and observe how the disorderly mixtures of the world are turned into orderly patterns and artifacts (1987: 15). Latour's capacity to work fluidly across the empirical and the conceptual, to link metaphysics and methods, is arguably the most distinctive aspect of his project. Working sometimes from concrete empirical observations in the midst of the action, sometimes reconstructing case studies from the history of science, the emphasis is on accurately describing how people get on with the task at hand in particular settings. Latour's laboratory anthropologies made a dazzling methodological contribution to science and technology studies, helping to push the field towards the observation of practice and what scientists do, and away from the abstract certainties of the philosophy of science and the retrospective constructions of what scientists say.

Later, the Latour of *Reassembling* sought to set out new methods for a 'sociology of association' and for a descriptive social science more generally. Although its subtitle is 'An Introduction to Actor-Network-Theory,' the book explicitly asks to be read as a 'travel guide' or a 'how to book' (2006: 17). If society does not exist as a discrete entity that preexists social things (action, identity, processes, change), then it cannot account of itself for anything. For Latour there are 'no powerful

agents hidden in the dark' that can explain things (2004: 228). We will have to identify new tools and tactics to find out how the social gets put together. Latour argues that this means describing all the elements and tracing all the connections in a network or assemblage, starting with the actants involved in it. This means new methods and even a new job description for social scientists. We should not see ourselves as combative critics who reveal underlying structures and forces, or as clever interpreters of peoples' meanings. Turning the lofty ontological claims associated with ANT into something more modest and humble, Latour instead invites social scientists to see themselves as ants: "blind, myopic, workaholic, trail-sniffing, and collective traveler[s]" (2005: 9). As ants we would travel very slowly across and through the terrain of a network, noting all the connections, taking no shortcuts. Real knowledge rests on faithful attention to what is there and what all the actors (human and nonhuman) are doing. Whatever we think of Latour's philosophical and ontological pronouncements, his methodological prescriptions are always rigorous and often surprising. And he reminds us that the currency of our own methods, like those in any actor-network, is effort and work, not unique epistemological insights or special cognitive properties.

Following Latour Around: Alliances, Impacts and Further Travels

Latour's influences combine the philosophical with the methodological. He has drawn productively on Whitehead's pragmatic philosophy and insistence on the primacy of process and event, as well as on Deleuze's invocation of a flat world composed of multiple assemblages. Latour's conversations with the philosopher Michel Serres (Latour and Serres, 1995) draw out a shared concern with how translations are made between different kinds of knowledge and actions, and a particular interest in 'quasi-objects' and other in-between entities. His work draws on ethnomethodological sociology to develop a focus on practical action and lay reasoning (especially the work of Harold Garfinkel), and his laboratory studies drew him into an engagement with ethnographic and participant observation methods in anthropology. Beyond this, however, Latour is mainly critical of mainstream sociology. He is dismissive of the French positivist tradition founded by Emile Durkheim, and frequently suggests that sociology would have done better to adopt Durkheim's contemporary Gabriel Tarde as an alternative founding father. He is also opposed to critical theory, Marxist sociology, and some strands of postmodernism, although there are parallels with post-structuralism and especially Foucault throughout his writing (for an interesting account of this see Kendall and Wickham, 1999). He has a complex relationship with Pierre Bourdieu, whose early emphasis on exploring a theory of practice and ethnographic approach shares much with Latour's project, but whose later structuralist and critical turn is relentlessly criticized (2005).

As we have seen, Latour is closely associated with ANT or actor-network-theory. This approach emerged in science studies in the 1980s to account for things – entities, relationships, institutions – in terms of their connections. John Law (1999: 3) has said that ANT can be understood as the "ruthless" application of the relational and antiessentialist logics of semiotics beyond language to the material sphere (Law, 1993: 3). ANT highlights the performative nature of reality, showing how what appears durable, patterned, and stable is rather the contingent outcome of constant acts of making and remaking. ANT is probably best understood not as fixed theoretical position but as a loose assemblage of related concerns and assertions. It has indeed reassembled itself repeatedly, not least through critical reflection on its own precepts (Latour, 1999; Law, 1999). Latour himself has been very active in ensuring that ANT does not ossify into a framework of abstract concepts. He has half jokingly 'recalled' the label (Latour, 1999), both taking it back and suggesting the alternative name actant rhizome ontology. However, as we have seen, Latour then reclaimed the name and the method, at the same time puncturing some of its more grandiose and obscure connotations. Thus ANT continues to trouble our ontological assumptions at the same time as Latour asserts that it is nothing more than adopting the humble and modest methods of ants.

Latour has recently said that he was overwhelmed by the 'after-sale service' required in the light of the success and notoriety of ANT (Tresch, 2013: 303). This involved addressing critiques from both scientific realists and social constructionists in relation to his relational realist approach. The former group, fighting what have become known as the 'science wars,' allied Latour with deconstructionism and antifoundationalism, and accused him of an absurd rejection of the real (Sokal and Bricmont, 1998). At the same time, Latour's insistence that objectivity concerns precisely how things object, and his willingness to treat nonhuman actants symmetrically with human ones, seemed to many sociologists of scientific knowledge a step too far toward granting agency to unreflexive, unintending entities (Collins and Yearley, 1992). But all the while Latour and ANT were being avidly taken up by researchers within science and technology studies and beyond. In STS (science and technology studies) Latour and ANT reshaped the field, offering new ways of thinking about knowledge as real *because* it is constructed and new ways of studying practical action in specific sites. ANT has been attractive to geographers interested in rethinking the physical/social divide and in the spatial implications of network approaches. ANT is also increasingly present in organization and management studies, where its focus on the active work of ordering and organizing multiple actors in complex chains and networks offers an alternative to approaches based on structures and levels.

Conclusion

Latour's project moves between ontological questioning, empirical analysis, situated methods, and political speculation. He gives us radically new ways of thinking about a mixed-up world that are becoming more insistently relevant as Western societies begin the process of facing climate change. He shows how we 'nonmoderns' have inherited an amazing capacity to generate novelty and hybrids and an equally startling failure to recognise and take responsibility for them (2004; 2013). In the

face of a new reckoning with our transformed 'natural' environments, Latour is right to argue that this denial cannot go on. Philosophically, he gives us a real alternative to the circular nature of postmodern debates about epistemology and signification and a chance to rethink life and materiality. Methodologically, he pushes us as social scientists to be more faithful to what we can observe in the world, but to always be on the alert for the "slight surprise of action" and the need to recognise what is genuinely new in our world. (1999: 266). It is not quite clear that the social sciences have recognized it yet, but Latour's intervention in our worlds and our ways of thinking about them is already making transformative associations across our fields.

For those interested in following Latour's ideas back to the texts they came from, I offer here a highly selective reading guide. One place to begin is with the important trilogy of books on scientific practice, science studies and knowledge politics that span roughly the first twenty years of Latour's career. They are: *Laboratory Life* (Latour and Woolgar 1986, first published 1979); *Science in Action* (1987), and *Pandora's Hope* (1999).

Then there are three important philosophical and political texts produced at roughly 10-year intervals investigating the wrong turn taken by the modern constitution and its implications for social science and environmentalism. They are: *We Have Never Been Modern* (1993), *Politics of Nature* (2004), and *An Inquiry into Modes of Existence* (2013).

Looking only at the major books tends to focus on big theoretical claims at the expense of a sense of how often they emerge out of intense and generative engagements with very particular objects, people, and case studies. Here the reader might be interested in Latour's compelling exploration of Pasteur and his microbes in *The Pasteurization of France* (1988), or his examination of a guided transport system that never got built in Paris in *Aramis, or, the Love of Technology* (1996). It also misses Latour's collaborations with others through cowriting, conversation and contributions to edited collections. With Peter Weibel, Latour edited a wide-ranging and multifaceted collection of essays on how things become objects of political and civic concern, *Making Things Public: Atmospheres of Democracy* (2008); and we have already mentioned his conversations with Serres in their 1994 collection.

And it misses Latour's collaborations with others through cowriting, conversation and contributions to edited collections:

Focusing too narrowly on Latour's books can also obscure the fact that for many readers, especially in STS, Latour is best known as an essayist. His shorter pieces serve as excellent introductions. Latour's style and his interest in concrete objects and issues suit the form exceptionally well. He is adept at taking an idea and a reader for a rhetorical walk, provoking and entertaining along the way, and returning us to where we thought we had started only to find that we are somewhere else entirely. Here I want to mention three examples, spanning some twenty years.

The essay 'Give Me a Laboratory and I Will Move the World' (1983) takes apart the idea that scientific knowledge is either the outcome of neutral and pure methods or a product of social or political interests. Instead, it suggests, we might try seeing sociology in the very content and doing of science, and recognize microobjects in the lab as brand new sources of large-scale power.

In 'Where are the Missing Masses?' (1992), Latour dwells on mundane objects, including a seat belt and a 'Berliner key.' We delegate to them not only practical tasks but also morality – these objects keep us safe and maintain social borders. Latour argues that humans are neither wholly in control of our technologies nor dominated by the object(ive) worlds we create. Rather, we are cocreators and coinhabitants of a human/nonhuman collective. Ought not our social theory treat the missing masses more like we treat people?

In 'Why Critique Has Run Out of Steam,' Latour asks the social sciences to leave behind the deconstructive and debunking epistemology that has dominated from critical Marxism to postmodernism – without adopting its apparent opposite, a naïve realism concerned with external matters of fact. Instead we should deal with "matters of concern" and cultivate a "stubbornly realist attitude" (2004: 232) that is at the same time capable of dealing creatively with a constructed world.

Law and Aging

Israel (Issi) Doron, University of Haifa, Haifa, Israel

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by L.A. Frolik, volume 12, pp. 8426–8429, © 2001, Elsevier Ltd.

Abstract

Law and aging is a new and developing field of knowledge. It is both multi- and interdisciplinary by nature. It combines theoretical and practical knowledge from the fields of law, gerontology, and geriatrics. It focuses not only on legal interests of older persons and their family members, but also on substantive legal issues, which are of importance in old age (e.g., guardianship, social security, or health law). As described in this article, law and aging is a rich and diverse field, which has novel elements in both international law as well as municipal and local law.

What Is 'Law and Aging'?

The phrase 'law and aging' can actually carry various meanings (Morgan, 2010). It can mean 'elder law,' which is a specific field within the legal discipline that focuses on the legal issues relevant to the older population, their families, and caregivers. This could be called a 'population-based' or 'client-focused' definition: it focuses on the target population and clientele, and defines its field accordingly. It assumes that 'older persons' can be identified as a unique social group, and that this social group has unique legal interests that can be defined and categorized as elder law. According to this approach, the clients are the one who define the field of practice (Kohn and Spurgeon, 2010).

Unlike the population/client-centered approach, a different conceptual approach to elder law can be found in a 'value/topic-based' definition: it focuses on core values (e.g., autonomy, dignity, or quality of life), and organizes a 'list' of substantive legal topics that ensure these values in old age (NAELA, 2010). Historically, fields such as poverty law, social security law, housing law, or health law were all considered a part of 'elder law.' In the United States, for example, elder law was developed to some extent through 'topic-specific' practitioners (e.g., in the field of social security or health law), who transformed and broadened their interests beyond their initial expertise in order to promote the human rights (HR) and dignity of older persons.

A different conceptual approach focuses less on the legal interests of older persons or the substantive fields of law that relate to them. A more sociological approach to the field of law and aging (also known as 'jurisprudential gerontology' or 'geriatric jurisprudence') focuses on the social interaction between aging processes, the social construction of old age, and legal institutions. Its origins are in the sociology of law, and it is interested in power relationships, social phenomena such as ageism, and how law and ageism interact in real life (Eglit, 2004).

For the purposes of this project, we adopt a broad and inclusive definition. Law and aging in this article is meant to be a broad, 'umbrella' term, referring to a multi- and interdisciplinary field of study, which includes the different and diverse empirical and conceptual interactions between legal institutions, norms, and theories, with the social phenomena of aging and its accompanying multidisciplinary science of gerontology and geriatrics. In this sense, a guardianship order over an older person handed by local courts; the psychological and economic implications of mandatory retirement laws; policy research about the rates of involvement of older drivers in road accidents with reference to the legal regulation of drivers licenses; or the study of the medical dilemmas around physician assisted suicide – are all well within the field of law and aging.

It is worth noting that there are critics who question the justification of the existence of 'elder law' or 'law and aging' as a valid field of legal knowledge. The most basic argument in this context is that law should not be different for a person over 80 years of age as opposed to a person of 45 years of age. Moreover, to the extent that law is indeed different, it only reflects – and reinforces – ageism, and hence should be avoided as a proper policy. Moreover, 'older persons,' as a group can only be characterized in their diversity and incoherence, therefore, there cannot be a rational justification for this field of knowledge. These criticisms have merit. However, in the real world, old age remains a strong socio-legal-policy construct (like gender and race). Ignoring this reality or turning away from the role that law plays in constructing old age, does not serve older persons or our understating nor can it allow us to change or legally combat ageism (Herring, 2009).

A Short History of Law and Aging

The field of 'law and aging' (or 'elder law') is relatively new (Bogutz, 2009; Frolik, 1993). It was 'recognized' as a distinct field within the discipline of law, only 40 years ago. Its historical roots were based on various legal and social interests. On the legal side, one base was lawyers specializing in wills and estate planning, which was broadened into the complicated Medicaid planning. In light of the dramatic change of demographic aging, these legal practitioners sought professional recognition of their specialty, as well as tools for professional development. A different interest base was also found in lawyers dealing with poverty law, and rights of the poor and elderly, in fields such as social security, housing, and health law. Lawyers and legal scholars began to recognize a need for unique and special attention for the legal needs and interests of older persons and their families, especially as the baby-boom generation started to face old age and legal issues around aging.

But not only practitioners were interested in this new field, academics, legal scholars, and gerontologists were also starting to look into the interactions of law and aging from both theoretical and empirical dimensions, and from an interest in developing novel fields of law. These efforts and recognitions culminated in the establishment of various professional organizations and nongovernmental organizations (NGOs). For example, the American National Senior Citizens Law Center was founded in 1972; the American Bar Association's Commission on Law and Aging was established in 1978; and the American National Academy of Elder Law Attorneys was formed in 1987 (Morgan, 2010). These associations were soon accompanied by the development of academic courses and law clinics and eventually by law journals in the field (e.g., *The Elder Law Journal* (first issue published 1993); or the *Marquette Elder's Advisor Law Review* (1999)).

This American legal development was slowly acknowledged and adopted in other common-law and English-speaking countries as well. In Canada, for example, consciousness of the existence of this field began to crystallize in the 1990s (Beaulieu and Spencer, 2000; Doron, 2003a; Soden, 2005). This has culminated in the establishment of the Canadian Centre of Elder Law Studies in the early 2000s, which has initiated academic conferences, research studies, and scholarship in the field. Finally, in Australia, a center for elder law was established at the University of Western Sydney at the beginning of the new millennium, and alongside it, a new *Elder Law Review* journal was founded (first issue published 2002) (Field, 2005).

European jurisdictions (in contrast with North America) have only very recently 'joined' this trend (Evrard and Lacour, 2012). Books or articles referring directly to the field of 'elder law' or 'law and aging' – as such – have only very recently begun to be published. Interest in the field was starting to emerge in European and other countries, including the United Kingdom (Herring, 2009; McDonald and Taylor, 2006; Meenan and Broadbent, 2007), Israel (Doron, 2007), and more recently in France, Belgium (Evrard and Lacour, 2012), and Germany.

Mapping the Field of Law and Aging: A Multidimensional Model

Over the years various theoretical perspectives have been proposed to provide a broad conceptual understanding of the field. Such perspectives have included: a feminist approach (Dayton, 2008); a therapeutic approach (Kapp, 2008); a law and economics approach (Kaplan, 2008); a disability studies approach (Surtees, 2008); a later life planning approach (Frolik, 2008); an equity approach (Hall, 2008); or a mental health theory approach (Schmidt, 2008).

One of the models that provide a broad and inclusive perspective on the field is known as the 'multidimensional model.' This model is an ongoing project, which continues to be developed and studied (Doron, 2003a, 2008a; Doron and Kohn, 2011). This model is presented in **Figure 1** below.

As shown in **Figure 1**, and as described by Doron and Kohn (2011), the model consists of five different elements, as follows: The 'Legal Principles Dimension' recognizes that rights of older persons can be viewed through the lens of general and nonage specific principles and doctrines. For example, values and equality and antidiscrimination can be applied in order to promote the rights of older persons without having to 'create' novel or unique rules. One of the more well-known examples within this dimension is the struggle against age discrimination in old age. Hence, promoting rights of older persons through antiage discrimination legislation is a clear implementation of 'core' legal values such as equality or dignity. These values do not attempt to 'treat' older persons 'differently' but rather argue that they should be treated like any other member of the society and not discriminated against only due to chronological age.

The 'Protective Dimension' reflects the understanding that sometimes the universal dimension is not enough, and some unique and specific rules are needed to protect older persons. Such legal measures are especially relevant to combat or address complex social issues such as elder abuse, self-neglect, or poverty in old age. Well-known examples for this dimension can be found in adult guardianship legal instruments, adult

Figure 1 The multidimensional model. Source: Doron, I., 2003b. A multi-dimensional model of Elder Law: an Israeli example. Ageing International 28 (3), 242–259.

protective services mechanisms, mandatory reporting laws, or quality assurance regulations of nursing homes. Such laws authorize socio-legal interventions that can prevent and discontinue abuse or neglect of older persons, while providing solutions that enable providence of care.

The 'Supportive Dimension' mirrors social gerontological knowledge regarding the importance of informal care and social networks to the quality of life and health of people in old age. This knowledge presents a challenge to legislatures and policy makers to both mandate and encourage family members to care for their older parents and family members. Such legal policies may allow family members to take paid leave in order to care for the older parents; they may provide tax incentives or discounts for informal cares that provide care for dependent older adults; or, they can provide paid respite and relief for the caregivers themselves. By providing the tools for promoting and supporting social support systems, systems that the gerontological literature indicates can play an important role in promoting older persons' well-being and elder self-determination. These third dimension laws have the potential to improve significantly the lives of older adults.

The 'Preventive Dimension' stresses the important role law can serve as a preventive social tool in old age. In many countries, law now provides ample tools for various realities of old age, such as planning for the loss of mental capacity, or planning for the need for long-term care. Some of the well-known instruments of this dimension include legal tools such as 'durable powers of attorney' (also known as 'enduring/continuing powers of attorney') – which allow individuals to plan for future financial decision making. Others – such as health care proxies or living wills – allow individuals to plan for health care decision making. Specifically, a health care proxy (also known as a power of attorney for health care) allows individuals to appoint someone else to make decisions for him/her in the event he/she is unable to do so for himself/herself. All these legal tools can play a crucially important role in enabling older individuals to make autonomous, individualistic choices about their own lives. These personal planning tools are flexible in that they can be easily adjusted to correspond to the particular needs and desires of the individual. They also have the potential to be sensitive to ethnic, cultural, and moral differences in that they do not prescribe a particular course of action, but rather permit decisions to be made based on individual preferences and values.

Finally, the 'Empowering Dimension' stresses the known fact that merely adding rights to the law on the books is insufficient to change reality. One needs measures such as advocacy, legal representation, knowledge creation, and distribution, in order to actually make a difference in the lives of older persons. An example of an empowering legal policy is mandatory representation of older persons in guardianship proceedings. In light of the far-reaching legal consequences of imposing a guardianship over an individual, most US states require the allegedly incapacitated person be represented by either legal counsel or a guardian-ad-litem at the hearing (American Bar Association Commission on Law and Aging, 2009). Such counsel is important both for remedying potential power imbalances, and for ensuring that those subjected to guardianship proceeding are afforded due process of law.

The multidimensional model emphasizes the diversity and variability of legal systems' responses to aging and the concerns of older adults. The model suggests that the field of law and aging is composed of many distinct types of laws designed to meet the needs of older adults. The model also suggests that elder law reflects a range of political and philosophic approaches to meeting the needs of older persons. The field is by no means directed by a single viewpoint. Accordingly, it should not be considered either 'individualistic' or 'paternalistic,' nor should it be portrayed as promoting 'negative' as opposed to 'positive' rights, or as favoring the individual over the family, or as privileging the private over the public. Rather, elder law encompasses a broad range of possible approaches and perspectives, and a given legal system's approach to 'elder law' can be fully appreciated only by understanding how that system weighs the different components – or dimensions – of the field of law and aging.

International Elder Law

In recent years the field of law and aging has undergone what can be described as the 'internationalization' of the field. This has been the outcome of a call made by various scholars (e.g., Doron, 2006; Doron and Apter, 2010; Doron and Spanier, 2012; Rodriguez-Pinzon and Martin, 2002; Tang and Lee, 2006).

Comparative Elder Law

Various legal systems around the world approach the range of law and aging issues in very different ways. In recent years there has been a growing interest in studying and comparing these different legal approaches by using comparative law methodologies. Comparative law can be a powerful tool to both better understand one's own legal system and values while realizing that other legal options do exist.

There are many recent examples of comparative elder law research. For example, a comparative legal study in the field of elder guardianship revealed totally different conceptual approaches to this legal institution. On the one hand, one can find a 'North American' approach to adult guardianship, which is focused on 'substitute decision-making' models; while on the other hand, a more European/Continental approach to adult guardianship is focused on assisted/shared decision-making models (Doron, 2002).

Global and Regional HR of Older Persons

Since World War II there has been a proliferation of HR instruments. Interestingly, older persons are one of the few populations that still do not have an HR convention of their own. An analysis and review of the international rights of older persons published in 2002 by Rodriguez-Pinzon and Martin (2002) summarized the legal field in this area as follows:

> A strategy to have a comprehensive legal instrument on elderly rights is missing at the international level in both universal and regional systems. There are very few provisions in international law that

> directly address elderly rights. There are isolated efforts by certain international bodies to systematically refer to the rights of the elderly when interpreting their corresponding conventions …
>
> However, there is no specific international body with the mandate to focus on the rights of the elderly. Nor is there an elderly rights convention in place. It is in fact the only vulnerable population that does not have a comprehensive and/or binding international instrument addressing their rights specifically. (p. 1008)

However, recent years have been characterized by a movement to change this reality both on the global/UN level, as well on the regional levels (e.g., Organization of American States (OAS), African Union (AU), and Europe). At the UN level, a symbolic and important point of reference was made at the UN Expert Meeting Group that was held in Bonn, Germany (April 2009). The international group of experts in the field of elder law held in-depth debates that resulted in various recommendations with regard to the advancement of the rights of older person, including a specific reference to the need for a new convention:

> A convention on the rights of older persons would add additional weight in furthering, deepening and more precisely defining the rights of older persons. A convention would create obligatory and binding international law. Similar to the adoption of various other human rights instruments, member states would undertake a threefold commitment when adopting such a convention: to respect, to protect and to fulfill the rights enshrined in the relevant text.

This recommendation was followed by a series of UN resolutions (UN GA R. 65/182) culminating in the establishment of the Open Ended Working Group (OEWG) on strengthening the protection of the HR of older persons. The OEWG held its first meeting in New York in April 2010, and held its fourth meeting in August 2013. Only time will tell to what extent this working group will be successful in moving forward the future International Convention for the Rights of Older Persons (OEWG, 2013).

While at the UN level the OEWG is still struggling with the question as to whether there is a need or a justification for a new convention, some regional organizations and agencies have move forward much quicker. The most startling and promising advancement was made in this area at the OAS. The General Assembly, through its resolution AG/RES. 2654 (XLI-O/11), "Protecting the Human Rights of Older Persons," adopted at the fourth plenary session on 7 June 2011, resolved, in operative paragraph 1, the following:

> To request the Permanent Council to establish a working group composed of national representatives and experts from the academic sector and civil society, as well as from international organizations and specialized agencies, to prepare a report by the end of 2011, analyzing the situation of older persons in the Hemisphere and the effectiveness of binding universal and regional human rights instruments with regard to protection of the rights of older persons.

Meanwhile, the AU has also moved forward very quickly on this front. Starting in 2007, the African Commission on Human and Peoples' Rights, decided to establish a Focal Point on the Rights of Elderly Persons in Africa (which was later transformed into a Working Group on the Rights of Older Persons and Persons with Disabilities in 2009 (*ACHPR/Res.143 (XXXXV) 09*)). Among others, a primary role of this working group was "Spearheading the process of drafting a Protocol on the Rights of Older Persons for submission to the AU Policy Organs for consideration and adoption as soon as possible." A preliminary Draft Protocol was presented to the African Commission during the 48th session held in 2010 in Banjul, Gambia.

As of this time, none of the above international or regional initiatives have transformed into final or binding legal instruments. However, there is no doubt that it is only a matter of time until these initiatives will eventually crystallize into an official and binding HR instrument for older persons, a development that will change the international landscape of law and aging.

Private International Law

Globalization and the movement of older persons around the world for various reasons (old age migration; sun-belt migration; elder-care migration, and more) have given rise to the need for private international law solutions for new and complex legal issues concerning older persons. For example: which law will decide the validity of a will made by an American widower, who moved to live in Sweden in old age with his newly met partner, but has property in Canada? Or should the Japanese courts honor advanced health care directives made by an English citizen under English law, but who suffered a stroke during a visit to his son in Japan? And how should the tax and social security authorities in Germany deal with an Argentinean citizen, who worked in Greece for many years, but decided to retire in Germany, and receives a pension from Argentina? These questions and more can and should be answered by the substantive law in the field of private international elder law.

An example in this field can be found in the Convention on the International Protection of Adults. This international private-law convention "applies to the protection in international situations of adults who, by reason of impairment or insufficiency of their personal facilities, are not in a position to protect their interests." The convention "aims to shield the vulnerable members of society by determining which state – that of their citizenship or of their current residence – may assert jurisdiction over them" (Fagan, 2002: p. 331). While not explicitly stated, it is clear that this convention is of significant, if not primary, relevance to older persons.

Municipal Elder Law

A novel development in the field of law and aging has begun to look into the legal potential existing in the powers of municipalities, cities, and villages to regulate and establish rights for their older residents. In an era of globalization, it is no simple matter to claim that decentralization and the broadening of the jurisdiction of local government are appropriate methods of promoting the rights of the older population. Nevertheless,

recent studies suggest that the power of local elder law is not incidental or residual. Local elder law can potentially be used as a strategic legal tool to change the position of older people in their communities. Local governments in various places around the world can play an important role as both leader and champion for community-based legislative initiatives to promote the rights of their older residents.

In a series of studies conducted in Israel, Canada (Doron, 2009), and the US (Dayton and Doron, 2012; Doron and Dayton, 2012), it was found that despite the potential legal powers that exist in the hands of local authorities, very little attention is given to the rights of older persons in this field. For example, in a national US study, the authors concluded that: "Unfortunately, our findings in this study suggest that local law is not currently fulfilling its potential as a means to expand the rights of older citizens. Few cities across the country appear to have taken more than minor steps in the direction of developing clear, ordinance-based policies that will truly foster age-friendly cities and committed public agendas for achieving the objective of 'aging in place' on a large scale" (Dayton and Doron, 2012: p. 116). Moreover, as described by the researchers: "The ordinances we found, that do explicitly acknowledge the needs and rights of seniors, tend almost entirely to fall within the most traditional spheres of local regulatory authority, such as land use laws and taxation. Many ordinances focus on age as a negative attribute; some arguably work to isolate and stigmatize age by relegating congregate housing options for compromised seniors to commercial districts or other nonresidential areas" (p. 116).

Jurisprudential Gerontology/Geriatric Jurisprudence

The article began by presenting the various definitional approaches to law and aging. One of the key differences between the 'elder law' as opposed to the 'law and aging' approaches is their relationship to gerontology and to other nonlegal disciplines. Gerontology (i.e., the science of aging) has been characterized by being inter- and multidisciplinary. It includes psychological, sociological, anthropological, and many other disciplinary perspectives on aging. Hence, the scientific and disciplinary cooperation between gerontology theories and empirical findings with legal knowledge has developed into what is known as 'jurisprudential gerontology' or 'geriatric jurisprudence.' This multi- and interdisciplinary approach has been gaining force in the current development of the field of law and aging (Doron, 2006; Kapp, 2003).

In a recent article, Doron and Meenan (2012) argued that geriatric jurisprudence is essential for the further development of the field of law and aging. Firstly, they describe what geriatric jurisprudence is: "It is a new interdisciplinary research approach that attempts to combine jurisprudence with geriatrics. It is not only the outcome of the meeting of lawyers, geriatricians, and gerontologists, but is the attempt to break down the disciplinary borders: an integration of the fields of knowledge based in geriatrics, gerontology, and law. The different scientific approaches enrich each other and enable one to better conceptualize and theorize complex socio-medical realities concerning older people" (Doron and Meenan, 2012).

Secondly, they provide the justification for the need for such an approach to the field of law and aging: "[G]erontology and geriatrics are, by nature, not only multi- but also interdisciplinary fields. One cannot, for example, address issues such as age discrimination in health care or advanced health care directives without taking into account not only the medical, psychological, or social conditions of older persons, but also the relevant laws and legal precedents that exist in these fields. Moreover, law is an important tool for social policy and social change. Law is an important ingredient of the social and cultural fabric of the society. One cannot fully understand the social and medical dimensions that are relevant to the lives of older persons without taking into account the legal implications whether speaking of empowerment, preemption, protection, or redress" (Doron and Meenan, 2012: p. 3).

Conclusion: The Future of Law and Aging

Law and aging is still an emerging field of law and society scholarship, struggling to be recognized as a legitimate unique field of knowledge. In this section we ask: what can we foresee in the coming years? In what directions will elder law develop? What are the new and promising directions that attorneys and advocates can promise to older persons? Some general trends can be identified and recommendations made as follows.

The Growing Interest in and Development of the Field

In many parts of the world 'law and aging' is still an unknown territory. It is not taught in law schools, nor in gerontological or geriatric studies. Even in countries where elder law and law and aging are known as distinct fields of law, they are still under-researched, and there is much room to further develop the empirical data and theoretical foundations of the field. From this perspective, it is clear that much academic and practical work is still needed in this field in order to establish its theoretical foundations.

More specifically, there is place for empirical studies that provide the necessary data to better understand the ways in which older persons experience law in daily life, and how judges and lawmakers construct old age in their legislative work and their case rulings. Greater cooperation is needed between scholars and practitioners to establish intellectual cross-fertilization of knowledge and practice. Finally, a stronger and richer body of 'third sector'/NGOs that specialize in this field and serve as advocates and activists of rights of older persons should be further developed.

International HR

It is quite clear that the coming years will bring great changes to the field of law and aging in the international arena, both globally and regionally. Both in the Americas and in Africa, the regional international bodies are deeply engaged in the establishment of new and novel HR instruments for rights of older persons. On the UN level, the opposing forces are still strong, yet there is a steady movement forward, with a push from NGOs around the world to continue and work for the establishment of a new binding HR convention for older persons.

These new developments on the international arena will directly influence the future of law and aging in many societies. Preliminary findings from supernational and international legal tribunals (e.g., The European Court of Justice and the European Court of Human Rights) reveal that older persons are using these legal forums and that they have the potential to serve as instruments for social change and the promotion of HR of older persons (Doron, 2013).

Legal Politics

The field of law and aging is also going to be strongly affected by the politics of aging (Hudson, 2010; Binstock, 2007; Vincent, 1999). This can be viewed from different angles. For example, one angle is the growing trend of national and local political parties of pensioners and senior citizens as well as elder-rights social movements (Kohn, 2010, 2012). These new political parties and social movements have begun to gain power and achieve political success, which can be translated into legislation, legal reform, and increased interest in the field. A different angle can be the socioeconomic construction of 'generational warfare,' especially around the funding of pensions, and wealth distribution between the younger and older generations.

The politics of aging can be reflected in legislative initiatives regarding rights of older persons. One such example can be found in Israeli politics and the legislative developments around Israel's Senior Citizens' Rights Act. A study conducted on this specific legislation (Doron, 2008b) concluded that: "The analysis of Israel's *Senior Citizens Act* affords no reason for political-gerontology optimism. The interest-driven reality of politics is reflected in the ways in which the law is 'brought to life' shortly before general elections, only to be allowed to 'die' again soon after. Prime Ministers and Ministers of Labor and Social Affairs show no interest in senior citizens, but use the law to create a caring image that lacks foundation. MKs (Parliament Members) are happy to laud Israel's older population. However, they are not willing to engage in a real struggle in the face of opposition from the Prime Minister or the Ministers of Finance or Social Affairs. Lastly, the legislature seems not interested in the actual implementation of the law, since image is far more important than the lives of old people" (Doron, 2008b: pp. 196–197).

As the interest in the 'gray force' of politics continues to grow, it will be important to continue to study how these political forces 'translate' into legislation, regulation, and legal rights of older persons.

Ageism and Law as a Tool for Social Change

Finally, an important role of the 'law and aging' field can be to provide tools for advocates of social change in combating ageism. Awareness of the social construction of old age and its manifestations in law – both negative and positive – is relatively recent (e.g., Eglit, 2004; Whitton, 1997). Yet, since the introduction of the term 'ageism' by Professor Robert Butler in the late 1960s, there has been a growing body of literature and research indicating the scope of ageism on all socio levels. Hence, similar to the role of legal scholars and scholarship in other movements for social change, for example, the feminist or the civil rights movements, the field of law and aging can provide an important foundation for the next civil rights movement, that of the older population. However, in order to serve that role, empirical and theoretical foundations need to be further established and strengthened – yet another challenge for the field of law and aging looking forward.

Law and Courts in Authoritarian States

Peter H Solomon, Jr., University of Toronto, Toronto, ON, Canada

Abstract

Authoritarian rulers need law and courts as instruments of rule, to perform such functions as social control, legitimation, administrative accountability, and encouragement of investment and trade, but more than their democratic colleagues they find it difficult to sacrifice political power. Consequently, they fashion weak and dependent courts, opt for fragmented jurisdiction (with special tribunals for matters of regime interest), readily readjust the jurisdiction of courts and judicial discretion when they are provoked, or create formally independent courts that are undermined by informal practices. Authoritarian rulers prefer narrow positivist understandings of law to avoid constraints but may face pressures to meet international standards for the protection of business or human rights. Rule by law rather than any version of rule of law characterizes the role of law in authoritarian states.

Law and courts play major roles in modern authoritarian states, as they do in democratic ones. At a minimum they perform the same basic functions of social regulation and the resolution of disputes, and they do so in a reasonable fashion in many instances. At the same time, though, law and its enforcement through courts often connect to the distribution and exercise of power, and it is through this nexus that significant differences across regime types arise.

As a rule, authoritarian states lack the features that define democracy, such as free and fair elections, observance of civil liberties, universal suffrage, and effective control of the state by elected officials. But the essence of authoritarianism in its various forms (including competitive authoritarianism and so-called hybrid regimes) lies in the concentration of political power in the hands of an autocrat or an oligarch. Whereas in Western democracies the law may serve as a constraint on the power of rulers as well as an instrument of rule, in authoritarian regimes the instrumental role tends to dominate, in some cases (and ideally) to the exclusion of a limiting role. Thus, while theorists may speak of 'rule of law (ROL)' as a feature of democracy (meaning not only procedural guarantees for the citizen but also constraints on leaders), the most convenient shorthand for authoritarian regimes is 'rule by law', a phrase that emphasizes law's role as an instrument of rule (Ginsburg and Moustafa, 2008).

One should stress that the availability of law as an instrument of rule for authoritarian rulers does not mean that they will act lawfully all or most of the time. They and their states may still "predate on their subjects, [or] violate property rights, and [they] are unbound by the strictures of law" (Darnden, 2008: p. 38). The same rulers may also promulgate laws that are not designed to be obeyed (Darnden, 2008: p. 38).

But the reality is that as much as authoritarian leaders may wish to maximize their power and avoid law's potential limits, in practice they end up making compromises. This is unavoidable if law and courts are to perform some of the functions that the leaders value, including legitimation of their rule. Moreover, leaders must maintain elite cohesion and popular consent, including the consent of liberalizing constituencies engaging in social mobilization (Svolik, 2012). Finally, in the late twentieth and early twenty-first centuries, leaders are facing global pressures to meet standards of legal protection, at least for business activities if not also for human rights.

Not surprisingly, then, in some authoritarian states the role and functions of law (even its meaning) are contested and involve tensions, if not also conflict. Such tensions are especially prominent in regimes where leaders claim legitimacy through the use of quasi-democratic institutions or in regimes that some might call hybrid or competitive authoritarian (Levitsky and Way, 2010). Such tensions also characterized authoritarian states in nineteenth-century Europe (e.g., Germany and Russia), where liberal political forces promoted judicial power to balance that of the executive.

This article starts with an examination of the role of law and the functions it may play in authoritarian contexts. It goes on to consider the alternative approaches that rulers take to the power and independence of courts, so as to maximize outcomes favorable to the regime in cases that matter to it. Then, the article illustrates ways that the pressures of the global economy and polity influence choices made by authoritarian rulers. Finally, it addresses briefly two unresolved issues – the utility of stretching the concept of ROL to fit some authoritarian states; and how to explain variation in the role of law and courts in authoritarianism.

The Law

For the authoritarian ruler, the most convenient understanding of law is limited to his own legal enactments, whatever they are called. The law consists of the laws of the state, especially the edicts or decrees of the ruler himself. However, few autocrats have had the luxury of gaining a monopoly on law in their time. Most feudal and early modern rulers in Europe faced competition from the realm of the sacred, or the domain of canon law, where they had little or no authority. (Norms of customary law were usually built into the laws of the state). Moreover, the idea of a source of secular law beyond the state and ruler – 'natural law' – had been in circulation at least since its eloquent articulation by the Roman orator Cicero. To be sure, the later Roman code of the Emperor Justinian placed the ruler above the law, satisfying the authoritarian urge. But even

the monarchs of pre-Enlightenment Europe confronted forms of legal pluralism and the idea of law beyond the state (Berman, 2003; Tamanaha, 2004).

From the Enlightenment, natural law theory became a justification and even a tool for limiting the power of monarchs and moving toward constitutional monarchy and democracy. While gaining popularity in France and America, the theory faced strong competition in Germany and Central Europe, where what would become known as legal positivism gained sway and became entrenched in the lasting conception of rechtsstaat. In Wilhelmian Germany, a liberal autocracy, the law consisted of the laws and not of preexisting rights or values, as some theorists of ROL averred (Ledford, 1993). In the twentieth century, most authoritarian regimes followed a positivist view of law as comprising merely of the laws, but this view was soon challenged by the new international law of human rights, itself an emanation of natural law theory. Once again, as we shall see, many authoritarian rulers had to yield part of their cherished monopoly of law, though in particular instances they resisted.

It is not uncommon for authoritarian regimes to have legislatures that, while controlled by the ruler(s) (or ruling party), have responsibility for adopting laws, thereby giving them a kind of functional legitimacy even though bureaucratic politics may account for the content of laws more often than legislative activity. But there remains the problem of the role of pronouncements that come directly from the leader(s), which may in practice take precedence over laws regardless of their legal status. Moreover, in some states (e.g., USSR/Russia), regulations issued by bureaucratic agencies often carry more weight than the laws that they are supposed to implement. The weakness (or absence) of legal hierarchy was a particular problem in former communist countries, and it has continued in many of their successors (Solomon, 2008). Finally, there may be occasions (even frequent ones) where informal practices or norms trump the formalities of law, legal procedures, and institutions. Conventional wisdom says that this happens more often in authoritarian than democratic states, if only because authoritarian states tend to be weaker.

Functions of Law in Authoritarian States

In authoritarian states, the primary role of law is that of an instrument of rule. It is, of course, one of many instruments, along with coercion or repression applied directly by police or the military. Of course, law can also serve as an instrument in the hands of individuals and social groups seeking to change policies or institutions, as part of the process known as legal mobilization. But in authoritarian states the balance among these functions favors the state, usually strongly. There remains room for different uses of the law by rulers. In some states the law delineates the privileges of particular groups or castes, thereby defining the social structure in a discriminatory way (e.g., Tsarist Russia before 1861 and Germany before 1877). In contrast, law can serve as an instrument of social change, even revolutionary change, as exemplified in the changes in property relations associated in Stalin's collectivization of agriculture and seizure of land. After the resulting upheavals and flight of peasants to the cities, Stalin turned to law again to stabilize the situation, inter alia through restrictions on movement of population (Solomon, 1996).

In their pioneering volume of essays *Rule by Law: The Politics of Courts in Authoritarian Regimes*, Tom Ginsburg and Tamir Moustafa identified four functions that law and courts often play in authoritarian states. Leaders use courts to: "(1) establish social control and sideline political opponents; (2) bolster a regime's claim to 'legal' legitimacy; (3) strengthen administrative compliance within the state's own bureaucracy machinery…; [and] (4) facilitate trade and investment…" (Ginsburg and Moustafa, 2008: Introduction). While these functions of law are commonplace and unremarkable in democratic states, they have special meaning in authoritarian ones and are not always easy to achieve, notwithstanding their increasing importance in some of them.

Managing the boundaries of politics and addressing challenges to them, both substantive and procedural, is a core task faced by rulers in all kinds of regimes, but the function has traditionally involved more consistent and intense activities by police and courts in authoritarian contexts than in democratic ones. Typically, authoritarian leaders restrict both the content of political discourse and the means of expressing views. They are also less likely to compromise with challengers by either accepting their demands or incorporating them into the political system. Just as in democratic states, so in the authoritarian ones the dividing lines between acceptable and unacceptable challenges and challengers are fluid, and the boundaries of politics change over time, depending upon the vulnerability felt by regime leaders. Thus, in the post-Soviet world peaceful demonstrations for causes that seemed acceptable before the Orange Revolution of 2004 in Ukraine appeared more threatening in the years that followed that event. After experiencing opposition protests on the streets across the country following the flawed parliamentary elections of 2011, the Russian government sought to stymie civil society initiatives through laws forcing nongovernmental organizations (NGOs) to publicize their reliance on foreign funding. The regime also engineered the prosecution and conviction of a leading opposition figure on dubious, if not trumped up, charges (Solomon, 2013).

The mechanisms used by authoritarian regimes for reacting to challengers they define as political deviants resemble those used in democratic regimes, but their content may differ. The political trial, whether held in regular courts or special tribunals, is more likely to reflect a strong bias in favor of conviction, and sometimes involves specific instructions. In the case of the famous Stalinist show trials in 1937 and 1938, where the accusations were contrived, the accused were pressured through torture into performing parts set out in elaborate theatrical scripts (Solomon, 1996). All of the accused were convicted and most were executed, and a similar fate awaited half of those prosecuted for state crimes in the special tribunals of the political police. In contrast, after 1964, Brazil's military dictatorship prosecuted a large number of its political opponents in military courts with the participation of civilian judges; over a 15-year period more than half of the accused were acquitted, and nearly two-thirds of those convicted received sentences of under 4 years imprisonment (Pereira, 2005). These examples point to the variety of ways that law and courts may be used in political policing and in the degree of judicial autonomy.

A second function of law, and reason to empower courts and even to make them appear autonomous, is the cultivation

of legitimacy for the regime. Authoritarian rulers cannot long rely on force alone; they need consent and support from the population, not to mention support from elites and comrades at arms. As a rule, stable and long lasting authoritarian regimes develop legal forms and institutions (including parliaments and courts, even elections of a sort) that curtail the image of arbitrariness in the system of rule. One of these is constitutions, and another more recent invention is constitutional courts.

Many, if not most, authoritarian regimes in the twentieth century chose to adopt constitutions, if only to set down guidelines for public administration and to give their rule normative expression. While constitutions are judicially enforceable in only a minority of authoritarian states (and even there within limits), the constitutions still matter for the rulers' relationships with the public and elites alike. A recent review of authoritarian constitutions identified four broad roles that they could fulfill. They can act as operating manuals, laying out the distribution of functions and responsibilities within the public realm. They can act as billboards, advertising the regime's purported strengths, values, and goals. They can serve as blueprints, outlining aspirations for a better future. And/or they can act as window dressing, describing institutions that lack power and rights that are nonenforceable. The constitutions in most countries have performed a mixture or blend of these functions, and the balance might change over time; in almost all cases, adoption of these constitutions led to some legitimation for the regime (Ginsburg and Simpser, unpublished book manuscript). Even the (in)famous Stalin Constitution of 1936, known for its articulation of rights that had no bearing on reality, performed the other functions in a limited way. It gave the Soviet public a sense that the period of disruption was over and promised stable and better times to come. For foreign observers attracted by the impressive list of rights, albeit to be observed only 'in the interests of the working class', the window dressing function dominated (Solomon, 1996).

To the extent that constitutions define the structure of power and locate the ruler on the institutional map, they also influence the way that informal politics is structured and determine patterns of patronage. Thus, constitutions that center power in a presidency give that institution larger-than-life importance in the world of informal institutions, often of crucial import in authoritarian contexts.

To cultivate legitimacy and to appear to have normal, even democratic regimes, authoritarian rulers not only issue constitutions but also create constitutional courts. This is especially likely when regimes enter a liberalizing phase or are trying to present their regimes as democratizing. This was the case in Egypt (in 1979); in Indonesia (in 2001); in Russia (1991), in Ukraine (1996); in Kazakhstan (1991); and in Belarus (1994). Even if judges on such courts act cautiously, taking initiative only in approved realms and within the parameters set by the regime, they may still prove too much of challenge for authoritarian rulers. Thus, it was no surprise when Kazakhstan in 1995 eliminated its constitutional court only a few years after its establishment. In the case of Egypt, the leader Mubarek was content as long as the court facilitated his economic program; when it began enforcing rights he quickly appointed a new Head of the court and expanded its membership to make the court compliant with his policies (Moustafa, 2007). For its part the Constitutional Court of the Russian Federation, after getting too involved in politics in 1993 and suffering temporary suspension, steered a careful course, avoiding decisions that contradicted the interests of the Russian President. The Court was able to carve out significant areas of action (e.g., defining the federal system and economic rights) and to develop a meaningful jurisprudence. Its biggest problem lay in securing implementation of its decisions by other governments, ministries, and courts alike (Trochev, 2008).

A third function of law and courts in authoritarian states is the promotion of administrative accountability. Whether they use regular courts, administrative courts, or tribunals within the executive branch, leaders derive two-edged benefits from administrative justice. On the one hand, they gain the support of members of the public who can successfully challenge decisions of officials that seem illegal; on the other hand, they are able to detect counterproductive, not to mention illegal, conduct on the part of officials and thereby improve the performance of government.

Authoritarian leaders, past and present, have come to value administrative justice and have been prepared to empower judges in this realm. Early examples include the Supreme Administrative Law Court of Prussia, which from 1876 provided legal controls over the actions of officials in an authoritarian state and helped bring their performance closer to the standards of the *rechtsstaat*, this despite a fixation on procedure. Within Tsarist Russia the Judicial Reform of 1864 produced, inter alia, a version of administrative justice in which citizens could bring suits against officials to commissions consisting of higher officials, although they had to collect damages directly from the officials themselves. Despite following the French model of separating administrative justice from the courts, this system worked reasonably well (Ledford, 2004; Solomon, 2008).

In Mexico under the rule of the Partido Revolucionario Institucional (PRI), or Institutional Revolutionary Party in English, citizens could complain to the courts about violations of their rights by officials through the mechanism of an amparo suit. The result was often satisfaction in individual cases, but rarely did the decisions have a broader impact because they were binding only between the parties (Magaloni, 2008).

For legal reformers in the USSR in the era of perestroika, strengthening the embryonic system of administrative justice was a priority (the USSR had relied on complaints to an administrative body – the Procuracy – rather than the courts). Soon after the country's disintegration Russia ended up with a capacious system of administrative justice, in which citizens could challenge in court the legality of almost any decision taken by an official, as well as the bulk of bureaucratic regulations. This area of the administration of justice worked particularly well in practice, and the bulk of petitioners won their cases in court and gained satisfaction in real life (Solomon, 2004).

The fourth function of law and courts for authoritarian rulers lies in the promotion of trade and foreign investment, by making investors confident that their property and interests will be protected. The rulers' desire to protect property rights and to create investor confidence lies at the root of the adoption of legal reforms in Asian countries like Singapore and China (Rajah, 2012). In contrast, the failure of law and courts to protect property rights in post-Communist countries like Russia and Ukraine make it clear that the economic interests of

state officials, reflected in state ownership of strategic economic firms and in a network of corrupt relationships, can trump concerns with creating adequate protection of property rights. At the same time, the creation of reliable forums for the resolution of business disputes and fair material and procedural law for them to apply does not mean that courts across the board will be autonomous or that other rights of citizens will be protected. As we shall see, concern with the needs of investors can lead to a bifurcation within the legal system, where parts operate close to international standards and other parts fail to meet minimal requirements of fairness (Fuller, 1969).

Courts

Authoritarian rulers need and use law to govern. As a result, they often end up empowering courts and judges by giving them some jurisdiction that matters (for example, political crime, administrative justice, regulation of business, and even constitutional questions). But authoritarian rulers do not easily yield power, and they may feel the need to ensure that judges deliver the 'correct' decisions in cases that matter to them. At the same time, to secure legitimacy, rulers need courts that have (or appear to have) a modicum of autonomy, if not some actual independence – that is, freedom from external influences. In short, authoritarian rulers experience tension between the need for some judicial autonomy and their desire to control the outcomes of cases.

Models of Judicial Power and Independence in Authoritarian States

In authoritarian states, past and present, one finds four common patterns or models of judicial power and independence, and sometimes combinations of them (Solomon, 2007). The first pattern, encountered in the USSR throughout most of its history, features both courts that were politically marginal (that is, given jurisdiction over a minimum of politically sensitive questions) and judges who were not independent (they faced multiple lines of dependency). Courts dealt with disputes among private persons and ordinary criminal matters, but not constitutional matters; they heard only minimal administrative cases, adjudicated hardly any business disputes (which were instead placed in the hands of executive tribunals), and until 1960 handled relatively few cases of political crimes, most of which were handled either by special bodies or military tribunals. Judges were dependent upon both political authorities at the same level of government and superiors within the courts. They faced regular evaluation and continuous need for reappointment (Solomon, 1996; Solomon and Foglesong, 2000).

The second model is what I call the Spanish solution, or a 'fragmented judicial system'. In Spain in the late Franco years the judiciary as a whole was independent; it had the normal set of institutional protections but its members lacked power or jurisdiction on all matters of interest to the government. These matters were placed in the care of a separate set of tribunals, whose adjudicators lacked the protections supplied to judges (such as life appointment and firing only for real causes). Judges on courts were part of a well-organized judicial bureaucracy where regular evaluations encouraged conformist behavior, but they did not suffer from outside interventions. This model may well embrace Salazar's Portugal and Mussolini's Italy, and it corresponds to a degree to Nazi Germany before World War II. In fact, it was in describing Germany that Ernst Frankel developed the concept of 'dual state' whereby some spheres of public life remained subject to traditional legal norms and others were politicized. The fragmented judicial system is especially common in states that have had a strong judicial bureaucracy and/or legal tradition (Toharia, 1975; Fraenkel, 1941).

Third come courts that are relatively independent and have politically meaningful jurisdiction created by authoritarian rulers. This model tends to generate tension or conflict, for when judges fail to support regime interests, they may face consequences. Wilhelmian Germany after the reforms of 1878 is one example (Ledford, 1993). Another is Tsarist Russia after the Judicial Reform of 1864, a place where judges (sometimes with the help of juries) made decisions that were intolerable to the Tsar and his circle, including the famous acquittal of a young female terrorist who shot and wounded the Governor of St. Petersburg. Not surprisingly, adjustments were made, including the removal of politically sensitive crimes to military courts, the declaration of regional states of emergency, and the cultivation of cooperative judges through increasing management of their careers (Solomon, 2008a).

Lastly, there are countries where courts are formally independent and empowered, but informal practices ensure that judges do not rule against regime interests. This category seems to include Singapore, which has convinced international business that it has a sound legal system, even though judges pay heed to regime interests, especially when political opposition is involved (Silverstein, 2008; Rajah, 2012). To a considerable degree, the laws (for example of libel) are written to facilitate this image. Another country that fits this model is post-Soviet Russia under Vladimir Putin. In this particular authoritarian state, courts have considerable autonomy and power, but informal practices ensure that Russian judges normally do the bidding of powerful persons in cases that matter to them. They do this sometimes for money, more often to keep the heads of their courts content with their behavior and to avoid any attempts to have them dismissed (Solomon, 2008a).

In Russia and many other post-Soviet states, the awarding of acquittals to the accused in criminal cases is discouraged by special reviews of the judges who give them and their frequent reversals on appeal, a negative in the evaluation of judicial performance and sometimes grounds for dismissal. In civil cases involving business, one side often has more political clout than the other, and the trial judge must pay heed to this reality to avoid conflict with the chief judge. Formally no judge may be dismissed except for cause (ethical breach, truly weak performance) and after review by his peers. In reality, the chairs of courts have sufficient leverage over the commissions charged with the discipline of judges that they can engineer the dismissal of any judge on a pretext (Solomon, 2010; Trochev, unpublished paper).

The first and second models (weak/dependent courts; fragmented judicial system) are both stable and straightforward;

the third (supposedly independent and empowered courts in authoritarian context) is unstable, featuring a constrained judiciary that faces threats to its independence and power. The fourth (courts that are independent formally but not in practice) involves a gap between formal institutions and reality, which may engender public cynicism and mistrust of the courts. It is also possible to envisage situations where there might be combinations of these models.

International Influence: Leverage at Work

Complex configurations of the relationship between law and courts and political power are becoming more common in the wake of international pressures that impinge on authoritarian leaders. In the late twentieth and the twenty-first centuries, few authoritarian states can survive without close ties to other countries, at least in their own regions if not further afield. And with those ties (for example, in the realm of business) go expectations about the nature of laws and the protection of the property of investors, if not also about human rights and the fairness of adjudication more generally. The closer the business ties with other countries or international organizations, the more leverage the latter can exert on authoritarian leaders so that they feel compelled to provide at least the appearance of laws and legal institutions that meet world standards.

The example of Singapore is well known, a country that has gone out of its way to court international business with promises of legal protections and a discourse about law that has earned praise for the country's commitment to law. At the same time, the administration of criminal justice, especially vis-a-vis rivals for power in various spheres, be they religious, journalistic, or groups of lawyers, is harsh and arbitrary. Through the criminal justice system Singapore's leaders have created an illiberal and repressive political order. To some observers, this contrast between the role of law in business and in criminal justice resembles the model of fragmented legal system, or a version of a dual state, where legality infuses some, but not all, areas of public life, and might be classified as 'authoritarian ROL' (Rajah, 2012). Another authoritarian state that seems to be experiencing a bifurcation in the state of its law and courts is China (mainland or communist China). Like Singapore, China has gone out of its way to transform its law relating to international business, trade, and investment. Many of these changes were either preparations for or consequences of China's accession to the World Trade Organization (WTO) in December 2001. Joining the WTO imposed obligations upon China to produce a liberal trading environment while protecting the rights of others (for example, in intellectual property rights). This entailed massive rewriting of domestic legislation on many subjects. At the same time, implementation of some new laws, especially regarding intellectual property, has proven slow and difficult. Intellectual property (IP) violations remain rampant; even the US government is critical of the mechanisms used by China to police property rights. At the same time, foreign businesspersons in China can face criminal prosecutions for breaches of legal norms that in most other countries would lead only to civil suits (Ya Qin, 2007; Bath, 2011).

While making concessions vis-a-vis the law of trade, customs, and intellectual property, China has maintained its authoritarian approach to law as an instrument of social control. China combines elements of a dynamic capitalist economy with an authoritarian and unreformed partocratic state. While its courts and judges remain even in formal terms far from independent and fully 'embedded' in the political order, under outside pressure China has engaged in elements of legal and judicial reform, aimed in the words of one observer at making courts "display a rational and professional outlook in the Western sense" (Liu, 2006). Yet the persistence and further flowering of informal practices ensures that judges pay heed to the interests of political authorities and conform to the norms of their peers. The situation of defense counsel is no better, as they are expected in practice to give precedence to cooperation with law enforcement over conducting a meaningful defense (Solomon, 2010).

At least three informal practices ensure that state interests predominate within the administration of criminal justice in China. First, individual judges (whatever protections they may have) rarely render decisions, especially in harder cases, which are left formally to three judge panels, whose members then informally consult with the head and senior judges of the court and, if necessary, judges on a higher court. Secondly, both the conviction and sentencing of offenders are influenced by periodic campaigns against particular kinds of crime. Thirdly, defense counsel who insisted on defending clients conscientiously and going beyond their conventional supporting role face the possibility of persecution by police, including beatings, illegal detentions, and even the opening of criminal cases against them (He, 2012; Solomon, 2010).

When handling civil disputes involving officials, Chinese judges readily change their policies to suit political needs. Legal reforms in the 1990s encouraged citizens to challenge the legality of official actions and thereby make judges key decision makers. But when too many petitions reached higher courts, authorities tried to prevent any threat to social stability by pressing trial court judges to achieve mediated outcomes that could not be appealed (Minzer, 2011).

In short, in China outside pressures to provide an adequate legal environment for business pushed authoritarian rulers to adopt a blend of a fragmented legal system and one governed by informal practices.

In contrast to China, the main outside influence on the administration of justice in Russia derived not from international business norms but from the global promotion of human rights. Because of its geographical location and its first leaders' desire to demonstrate democratic credentials, in 1996 the Russian Federation joined the Council of Europe, an institution devoted to making its members observe the European Convention on Human Rights. It is also equipped with a court to enforce its provisions: the European Court of Human Rights receives and rules on complaints coming from citizens in its member states and makes decisions that call for state authorities to both pay compensation and address the underlying problems that produce rights violations.

Over the years residents of the Russian Federation have brought thousands of cases to the European Court of Human Rights (ECHR), including complaints about violations associated with criminal procedure. Hundreds have been heard by the court and for the most part, rulings have been against the government of Russia. The government has usually paid the

fines to the petitioners, but it has not fulfilled the second part of its obligations, failing to take effective measures to reduce future violations. Russia continues to have the largest absolute number of complaints registered at the Court, although other countries (e.g., Ukraine and Turkey) may have the similar rates per capita population (Trochev, 2009).

This continuing saga has frustrated Russian leaders, at a minimum embarrassing them, at worst angering them. Why should a sovereign state representing a former great power subject itself to assessment by representatives of the international community? By Putin's second term in office (2005) Russia's leaders began having the decisions of the ECHR translated into Russian and circulated to most judges, in the hope that this would reduce violations and complaints. This did not happen; the number of complaints kept growing, in part because of the presence of NGOs that assisted Russians in bringing claims to the ECHR. For that reason, Russian leaders created an alternative domestic procedure for certain kinds of complaints: in April 2010, Russian courts were given the power to hear claims for compensation for violation of a party's right to a trial, and to provide funds for compensation. (A substantial share of the complaints to the ECHR coming from the Russian Federation had involved violations of this right.)

While the new procedure may have reduced the flow of cases to the ECHR by as much as 25%, it did not address the embarrassment felt by some Russian jurists and politicians of having their country's practices subject to criticism by a foreign body. The festering resentment boiled over during 2011. After the European Court of Human Rights dared to criticize not just the practice of an ordinary Russian agency or court but a decision of the Constitutional Court itself, its chair Valery Zorkin made the daring proposal that Russia and its Constitutional Court should be guided by its own understanding of the requirements of the Russian Constitution, rather than by the ECHR. Zorkin cited a decision from the German Constitutional Court stating that the lawmaker must have the right to avoid international legal obligations that would violate its own constitution (and therefore sovereignty). Zorkin's words aroused stern reactions from other Russian jurists, who understood that this approach violated Russia's treaty obligations. Not long after, the acting chairman of the Federation Council 'Senator' Torshin proposed legislation that would eliminate the priority Russian law gives to the ECHR, notwithstanding the fact that this would violate the Russian Constitution and expose Russia to possible expulsion from the Council of Europe. Torshin's draft was not adopted (Solomon, 2013).

The story of Russia's experience with the European Court of Human Rights constitutes an unusual instance of authoritarian rulers' confronting the exercise of power by a court outside their realm and resenting its exercise by that court. This ironic situation represents another example of how the development of global standards of justice along with institutions to enforce them could place burdens on and limit the power of authoritarian as well as democratic rulers.

Authoritarian 'ROL'?

One issue that has arisen in the study of law and courts in authoritarian states is whether one can or should speak of ROL in authoritarian states, at least with adjectives attached. In serious scholarship there is a distinction between a minimal, thin, or formal variety of ROL and the deep, thick, or substantive one. The thin or formal versions call for basic, but far from inevitable, features including: open and legitimate procedures for law making; consistent legal hierarchy (regulations subordinate to and implementing laws); transparency of laws and regulations; laws that are prospective, clear, consistent, and stable (if not also fair); and enforcement of the laws that is consistently just and impartial. The thick or substantive version of the ROL adds an important element to the minimal version: the law must also have a moral basis and be based on a normative foundation beyond the state and its laws, such as religion, natural law, or the international law of human rights. In the thick version of ROL, pravo (jus) consists of more than the laws (leges). It features legal principles and rights that the leaders of the state may not violate or contradict and that take precedence over their legal enactments. This implies that some Court or courts have the responsibility (and power) to decide when laws are not lawful (Tamanaha, 2004; Kleinfeld, 2006; Fuller, 1969).

As we have seen, authoritarian rulers are typically reluctant to yield major power to courts, and to my knowledge no authoritarian regime to date has met the standards for thick or substantive ROL. (None of the four models of courts and political power implies this). Nor have most of them approached meeting all the demands of thin or formal ROL, and it is not surprising that the editors of a pioneering book on courts under authoritarianism chose the title "Rule by Law". However, it may be theoretically possible for an authoritarian regime to approximate the requirements of thin ROL. Arguably, law and courts in Wilhemian Germany on the eve of World War I came close. The prevailing theory of *rechtsstaat* was consistent with thin ROL, and the forces of liberalism in Germany, including the legal profession, did what they could to promote it. Whether even the thin version of ROL could last for a long time in an authoritarian regime is far from clear, for there would be inevitable conflicts that could lead to either movement away from authoritarianism or from law.

For some scholars who study non-Western societies with authoritarian regimes, the misfit between ROL and normal politics seems to be based, at least in part, on cultural biases. Thus, the thick or substantive version of ROL, which prescribes limits on the power of rulers to violate individual rights, may well reflect values that are central in Western civilization but less important in other cultures. If one accepts this premise, then it may follow that one should not treat ROL as defined by Western scholars, in either version, as the only acceptable standard for non-Western countries, especially those with authoritarian regimes. For example, what should one call a state like Singapore that seems to meet the standards of thin ROL in the business sphere but not in matters of social control? To Jothie Rajah, one needs the designation 'authoritarian ROL' (Rajah, 2012). In an effort to identify models that have empirical purchase, Randall Peerenboom pictures three lesser versions of ROL in between full or liberal ROL and rule by law. He calls them communitarian ROL; neo-authoritarian ROL; and statist socialist ROL. Two of his qualified models of ROL include some limits of the power of the rulers (central to the spirit of ROL), while one does not. Two of them place collective

rights ahead of individual ones; and one gives more emphasis to strengthening the state. Peerenboom spells out each of the five models in considerable detail, so that other scholars can judge their utility (Peerenboom, 2002).

Variations among Authoritarian States: Competition and Informal Practices

Another issue in the law–authoritarianism relationship is explaining variations in the role of law and courts in authoritarian states. A number of factors might correlate with particular models of courts in authoritarian states, including: the age of a regime; its stability; the identity of the ruling group (individual, military oligarchy, a political party), the amount of competition it tolerates, and the strength of the state (or its formal institutions).

The factor that has received the most attention from analysts thus far is competition, especially the emergence within authoritarian states of new elite groups or more intense competition among elites. As I have detailed elsewhere, a series of studies has correlated judicial empowerment with political competition, in countries within Latin America and Asia, as well as within Europe centuries ago, although the relationship is not universal (Solomon, 2007; Trochev, 2010). Moreover, when the power of the ruler or ruling group is less certain, judges are more likely to resist fulfilling their demands, whether through the pursuit of a narrow positivist reasoning, strategic defection, or off bench political activity (Osiel, 1995; Helmke, 2004; Hilbink, 2007; Trochev and Ellett, unpublished paper).

Without doing a rigorous comparative study, one can still construct hypotheses about the other factors. Rule by a political party and/or with a discrete ideology may well connect to the first model of courts, where rulers keep full control over courts and do not empower them. Personal dictatorships, especially in countries that already had an autonomous judiciary, seem more likely to adopt the Spanish solution of a fragmented judicial system. This was the situation in Portugal under Salazar and Italy under Mussolini. The third model, in which autonomous legal institutions coexist with authoritarian rule and generate tension and conflict, is characteristic of older, stable regimes where there is some (liberalizing) group pushing for reform (Halliday and Karpik, 1997).

But it is the fourth model, where rulers create formal institutions that promise judicial autonomy but allow informal practices to undermine it, that may prove most in accord with the realities of the twenty-first century and most likely to gain prominence in the future. This approach is consistent with weak formal institutions, a characteristic of many authoritarian states in the developing world and post-Soviet space. It also fits with high levels of clientelism and corruption, another common (though far from universal) characteristic of authoritarian states (Zaloznaya, unpublished paper). At the same time, this model has the advantage of allowing authoritarian rulers to cultivate good reputations and public relations while retaining control over the administration of justice when needed. Remaining to be answered are such challenging questions as when and why many authoritarian states are weak, why they feature large doses of clientelism, and whether these conditions have a consistent impact on law and courts.

Conclusion

This analysis of the role of law and courts in authoritarian states and regimes underscores both their utility to authoritarian rulers as an instrument of rule (ruling by law) and the likelihood that the actual use of law and courts will make them yield some political power. In addition to needing law as a source of legitimation at home, authoritarian leaders often faced international pressures, if only to encourage trade and investment. It is difficult for authoritarian leaders to find a comfortable balance between their aspirations for control and the need to allow courts to rule against their interests, and most of the solutions to this dilemma involve contradictions and conflict. As a result, the administration of justice tends to be less stable and predictable in authoritarian states than in democratic ones. Rarely does it meet the standards of ROL even in its least demanding form. Rule by law remains the best description of its role.

Law and Democracy

Abstract

The complex and dynamic relationship between law and democracy has been a subject of interest since ancient times. In the contemporary world, the principle of democratic rule of law and the concept of law's legitimacy express the reciprocal and circular links between law and democracy. However, this relationship is not symmetrical. The fundamental task of law consists in controlling and even 'taming' democratic government against the possible misuse of power by the political majority. The relationship between law and democracy is increasingly problematic in all relevant dimensions: democratic participation in legislation, social and political subordination to law, and legal control of democratic government in order to protect rights and liberties of citizens. Contemporary challenges have been answered by new developments characterizing law: the growth in the power of the judiciary and the empowerment of citizens. The latter takes the form of the broad interpretation of the nondiscrimination principle and the protection of individual, and more recently also collective, rights. Therefore one can speak about the broadening and deepening of democracy. These new developments have been enhanced by the collapse of authoritarian and totalitarian regimes in Europe and elsewhere. However, one observes new phenomena consisting in the growing importance of subnational and international processes and actors. They present a new challenge to both democracy and law, and result in the fragmentation of relations between them.

The Relationship between Law and Democracy

The relationship between law and democracy is complex and dynamic. In general terms, democracy can be defined as rule by the *demos* ('the people,' i.e., by equal human beings who resolve their conflicts on the basis of procedures and laws agreed upon by themselves), and the law as more or less systematically ordered, formalized, and rational rules of conduct backed by the threat of force by those in political power when these rules are violated. What is decisive in the deep links between democracy and the law is the fact that the *demo*s – 'the people' – is the political source of the law to which it, in turn, subordinates itself. This takes the succinct form of constitutional principle of the democratic rule of law, present in a direct or indirect form in every liberal democratic constitution. In the contemporary world, the principle of democratic rule of law on the one hand, and the concept of law's legitimacy in democratic, liberal societies on the other, express the fundamental and reciprocal links between democracy and law. Thus, the interconnections between democracy and law are circular and twofold: the law legitimates the political power of democratic government, and democratic government presents the source of law, and makes it legitimate.

In Niklas Luhmann's autopoietic systems theory, these connections are reflected in the democratic liberal constitution as the highest binding law whose source is the democratic will of the people. The constitution establishes a 'structural coupling' between two differentiated subsystems (or partial systems) of society: the legal and political (Luhmann, 2004).

However, the democratic rule of law principle that expresses the relationship between law and democracy in contemporary societies implies that the position of law is higher and stronger. It is a task of law to protect not only its own goals, but also to protect democracy against its own 'vices,' against the untamed struggle of political interests, ambitions, wars of political factions. Therefore in the modern world courts of final instance increasingly decide not only legal, but also politically sensitive, matters.

These issues are becoming increasingly complex, and the concept of the democratic rule of law, as well as the idea of the democratic legitimacy of law, are undergoing changes inspired by the struggles for the protection of rights by individual and collective actors ever more conscious of their subjectivity. Thus, in modern liberal societies it is important to devise systems of autonomous and general rules to enable the protection of individuals and social groups struggling for their rights and the fulfillment of their interests against the misuse of power by democratic majorities, and to enable them to participate in the political decision-making process. In turn, the mutual links between democracy and law modified by the protection of rights have fundamentally important consequences for the legitimacy of law.

The relationship between democracy and law is further challenged by recent political, economic, and social phenomena: the emergence of supranational political organizations, like the European Union, the rapid growth of internationally active transnational corporations and nonstate organizations, and the growing importance of subnational, regional, and even local governments, associations, and organizations of local interests. To this, one should add the growing cultural pluralism of the modern world, which implies differentiated conceptualizations and interpretations of basic rights. Furthermore, the democratic rule of law debate is reinvigorated by the collapse of authoritarian and totalitarian regimes. These developments are inspiring new conceptualizations of government and law. They present a challenge to the classical democratic rule of law concept, and call into question the concepts of the political legitimacy of law and the legal legitimacy of government. The concept of *governance* rather than government has emerged on the agenda of political scientists, referring to the phenomenon of multilevel and complex systems of decision making, with participation by nonstate actors. New types of laws are debated by legal scholars, politicians, and lawyers. One speaks about the emergence of a third, and even a fourth legal order: a legal order of supranational associations of states, and a legal order that emerges in

form of agreements or regulations outside the state framework, affecting activities of supra-, inter-, and substate public, half-public, and private actors, across state boundaries and jurisdictions. Cultural pluralism and the differentiation of interpretations of the protection of human rights contributes to the debate on the democratic rule of law as well.

Important questions are emerging regarding the possible democratic deficit of these complex systems of governance on the regional (as in the case of the European Union) or even global level, and consequently, the possible deficit of the democratic legitimacy of nonstate law. Therefore, although the relationship between democracy and law has been debated in the West since ancient times, worldwide contemporary processes of globalization, the growing recognition of cultural pluralism, and the increasing structural complexity of the modern world greatly contribute to this debate, introducing new topics and new perspectives. Of particular importance as already mentioned, was the collapse of totalitarian and authoritarian regimes in the twentieth century in Europe and elsewhere. This article tries to identify the areas of common interest and disagreement in the debates on democracy and law, to summarize classical arguments on the reciprocal relationships between them, to shed some light on new incentives for the democracy and law debate, which result from the collapse of totalitarian an authoritarian regimes, and to reflect on the contemporary issues and challenges to classical concepts and institutional arrangements.

Areas of Common Interest and Disagreement

Many scholars and politicians, ancient, modern, and contemporary, have maintained that democracy, being a political source of law, cannot exist without law, since it would otherwise turn into anarchy. It is also argued that democracy represents a fundamental factor in the development of the law, since it has the unique potential to reflect and react to changing political and social reality. Democracy also contributes to the validity and legitimacy of the law: the law holds society together through the power of enforcement, but the legitimacy of political coercion derives from democratic legislative procedures. It must be stressed, however, that questions have been raised since ancient times about the possible misuse of law by a democratic power, in the form of a threat posed to individual sovereignty and creativity by the majority represented by the government. Presently, the relationship between majoritarian democracy as a source of law is critically reviewed from the perspective not only of individual, inviolable rights, but also of collective rights related to gender, and ethnic, racial, or religious minorities. This theoretical debate is translated into debate on the specific legal arrangements 'taming' democracy, on quotas or thresholds, i.e., on the visibility and 'voice' of minorities in democratic election and the lawmaking process, on the sensitivity and reflexivity of democratic legislation of the life experiences and lifeworlds of those, whose 'voice' could be silenced by the majority. New interpretations of such principles as nondiscrimination and equal participation and representation, equal treatment, or equal protection of rights appear which try to encompass different lifestyles, lifeworlds, and life experiences on the one hand, yet are rooted in 'local knowledge' – socially experienced interpretations of equal participation or exclusion – on the other.

In contrast to the flexibility and reflexivity of democracy as a political system, a certain 'gravity' is one of the law's characteristic features. Therefore, from the standpoint of the law, its relationship to democracy was never perceived as unquestionable or nonproblematic. The potential sources of disagreement were identified by David Held (Held, 1987: 2). From the point of view of political science, the primary disagreement lies in the definition of 'the people.' From the perspective of the law, this disagreement is summarized in a question: "Does the 'rule by' entail the obligation to obey?" (Held, 1987: 2). Answer to this question govern the principle of a democratic rule of law, or of a democratic state founded on the rule of law (democratic *Rechtsstaat*).

Positions taken in debates on these problems depend upon the model or variant of democracy, and on the type of society – whether it is a relatively simple, premodern society of the ancient city-state type, a functionally differentiated modern society, or a complex and pluralistic, culturally differentiated society characteristic of late- or postmodernity. There has been a process of broadening and deepening of the democracy concept – i.e., the broadening concept of rule by 'the people' that includes an ever-greater part of the society in the form of a popular franchise, and the deepening of a concept of the democratic state founded on the rule of law. Another related, controversial issues regards direct democracy in the form of referendum as a possible source of law.

At the beginning of the twenty-first century further new issues broaden the areas of interest and disagreement. The burning question emerges concerning *demos*, who are to be defined as 'the people' in the complex modern world characterized by overlapping organizational networks and competing loyalties that cross state boundaries. There appear also questions of the legitimacy of nonstate law, and the obligation to obey differentiated and complex laws issued on many levels of social organization and agreed upon by many procedures, not necessarily democratic in the classical sense.

Democracy and Law in Classic Debates: From the Ancient *Polis* to Liberal Democracy

Thinking about democracy and law in the West has been shaped by the issues and questions raised by ancient philosophers and politicians with reference to the aims, ideals, and the constitution of the *polis*, the ancient Greek city-state. These issues and questions do not just present a source of modern thinking about the relationship between law and democracy. They were also reflected in institutional arrangements, characteristic of liberal democratic regimes.

Three such issues are most relevant for deliberations on democracy and law: the civic and political culture (civic virtues); the rule of law, due process, and constitutional government; and the idea of superior argument in lawmaking and its enforcement. The latter idea demonstrates a foundation of the most influential contemporary theory on law and democracy, i.e., the theory of procedural democracy.

Among the ancient thinkers and politicians, one should mention Pericles, Aristotle, and Plato. Pericles emphasized that

respect for the law results from the lawmaking process by people who simultaneously subject themselves to an obligation to obey the law. The citizen's law, and respect for such law, lies in contrast to the arbitrary will of tyranny and subjugation to it through the use of brute force.

In his *Politics*, Aristotle (384–322 BC) observed that, if liberty is the first defining principle in the model of the democratic city-state, it had to be closely related to an equality of opportunity to hold office: only equal participation in legislation protects the freedoms and liberties of citizens. Therefore, liberal democracy relies on the possibility that every citizen has an equal opportunity to rule, which also justifies obedience to laws made by a democratic majority, even if free citizens want to live 'as they like' (Aristotle, 1981: 195–198).

On the other hand, the most important criticism of democratic rule was raised by Plato. In one of the famous dialogues – cited by sociologist of law Vilhelm Aubert in his book *In Search of Law* – Plato (427–347 BC) challenges democratic rule by raising the question: Why is the tyranny of the majority better than that of an oligarchy or of an individual? This question returns in every debate on the issue of majority democratic institutions protecting individuals and minorities from a potential majority abuse of power (Aubert, 1983: 6, 7).

Despite the intellectual potential and contemporary relevance of arguments raised by ancient thinkers, the institutional forms and ideas linked with the ancient *polis* have their obvious limitations. First and foremost, equality and freedom were restricted to those inhabitants of the city-state who were regarded as citizens, i.e., adult, male, and Athenian born. Women, immigrants and, above all, slaves, were excluded from this category. These ideas lacked the modern liberal fundamental conviction that all human beings are 'individuals,' and bearers of inalienable rights. Ultimately, their empirical terms of reference were based on a relatively small and structurally simple, homogeneous society whose economy was predominantly based on slave labor, and whose members could directly participate in legislative and juridical proceedings because of the small numbers involved and their affinity with one another. Nevertheless, the issues raised by ancient thinkers and politicians have set a framework for debate, as well as an ideal for institutional arrangements in modern times. In the contemporary debates references to these ancient issues continue to be made with regard to less authoritarian, more horizontal, and communicative models of political decision- and lawmaking procedures.

Questions and arguments concerning the relationship between democracy and the law have been especially important under conditions of rapidly growing social differentiation, of changes in social integration accompanied by diffusion of ownership, of a developing free-market economy involving the formation of a relatively broad class of producers and merchants on the one hand, and the growing complexity and centralization of an impersonal, bureaucratic state apparatus on the other. These conditions characterize the processes of social modernization and the formation of liberal democracy as known in the West. These questions and arguments are reflected in basic institutional arrangements, predominantly in the constitutions of contemporary liberal democracies.

There are two important issues connecting law and democracy within the set of institutional arrangements defined as liberal democracy: conflicting interests and the protection of individual rights.

In a rapidly changing, diffused society characterized by conflicting interests, relations between citizens and the state are reshaping the concept of the social contract. They require specific forms of law – through which compromises among conflicting interests can be struck. Moreover, they require a law with attributes of generality and autonomy in order to reflect changing social values and power relations. In the words of Roberto Mangabeira Unger, in liberal societies the law somehow accommodates antagonistic interests, and its procedures are such that anyone might find it in his or her own interests to subscribe to them regardless of the ends one happens to be seeking. Therefore, "The liberal type of social organization generates, and is reinforced by, a style of consciousness whose substance is the image of society as an arena of conflicting subjective interests" (Unger, 1976: 68–69).

Ideas concerning the notion of social contract as a foundation for political institutional arrangements, which accommodate antagonistic interests, and the delegation of legal sovereignty crucial for the validity and legitimacy of law and its observance are to be found in the writings of Thomas Hobbes (1588–1679). These ideas were developed and supplemented by John Locke (1632–1704), Charles Louis de Secondat, Baron de Montesquieu (1689–1755), Jean Jacques Rousseau (1712–1778), James Madison (1751–1836), Jeremy Bentham (1748–1832), James Mill (1773–1836), and John Stuart Mill (1806–1873).

Generally, according to proponents of the classic model of liberal democracy, the activities of a democratic government are to be limited and controlled, since the sole aim of the state is to preserve the 'life, liberty, and estate' of its citizens (Locke, *Two Treatises on Government*), or, as emphasized by John Stuart Mill, to protect the free development of the individuality of every citizen. This is possible in the form of a limited, constitutional government, subordinate to the law, whose activities are also subject to the mutual checks and balances of autonomous branches of government. In the highly developed Doctrine of Montesquieu, these are the checks and balances of the legislative, executive, and judiciary powers (Montesquieu, *The Spirit of Laws*).

In the public sphere of relations between citizens and the state, the idea of a contract concluded by free and formally equal citizens, together with the extended (initially to citizens understood as male property owners) franchise, legitimizes the political and legal sovereignty of the government. These ideas are closely linked with the notion of liberty, i.e., freedom within legal limits, and with the notions of natural, universal, and inalienable public rights of citizens whose activities are governed by reason, and who conclude a political contract and participate, directly or through their representatives, in the legislative process.

Classical thinkers located the source and foundation of individual rights and liberties in the idea of natural law as 'higher' than man-made, positive law. Thus they developed a concept of law, which limits political authority, even democratic political authority, with respect to human rights. However, the notion of natural law and its binding impact on positive law executed by a representative government was interpreted in various ways. Natural laws were defined as those discovered by

reason, i.e., by rational citizens acting under conditions of freedom, according to German philosopher Immanuel Kant. They were also understood to be of divine origin (Locke, 1960: 311). For Montesquieu, natural laws discovered by reason were to be interpreted in the context of local customs and traditions (Montesquieu, 1952: 32). The utilitarians Jeremy Bentham and James Mill declared theories of natural laws as the maximization of individual satisfaction whose source was the natural tendency of human beings to pursue individual happiness and interests and to avoid suffering (Bentham, *Fragment on Government*, James Mill, *An Essay on Government*).

One may conclude that with respect to protection of individual rights in the private and public domain, in the classic model of liberal democracy based on the primary importance of protecting individual property rights and the utilitarian maximization of individual profits, the 'haves' are protected first and foremost, and individual goals and interests dominate the constitutional, democratic state. The concept of equality proposed by the classic thinkers, and written into the first liberal constitutions, was therefore initially still very restrictive. Only persons who were property owners and male had a right to vote or to hold public office. Only John Stuart Mill wrote of a right to the development of individuality that made reference to women and minorities, and was connected with a postulated broad franchise (John Stuart Mill, *On Liberty*).

Different ideas about contract, the legitimacy of the law, civic virtues, civic commitment, and public government were proposed by the first representatives of the republican version of democracy. First of all, the notion of contract was here understood not as a legal fiction, but as a real contract closed by the people in the form of public debate and referendum on the most important public issues. The issue of civic virtue and of civic duties, and the notion of a *citoyen* as an unselfish, committed participant in public affairs was emphasized by Jean Jacques Rousseau. Accompanying this was the idea of a permanent social contract and direct participation in its formation as the foundations of social and political integration, the legitimacy of the law, and its observance. Here the claim to the legitimacy of a legal order could only be gained through the integrative force of the united will of all free and equal citizens. Advocating direct participation in legislation, and defining the equality of citizens as economic independence and material security, Rousseau opted for the model of a discursive democracy and referendum as its institutional form (Rousseau, 1973).

Liberal Democracy and Law: Contemporary Issues

"Liberal democracy was the first great secular religion in the Western history" writes Harold Berman (Berman, 1983: 32). However, large-scale, complex, densely populated, culturally pluralistic, and differentiated modern societies have developed new interest in and discussion about the relationship between democracy and the law. Four issues are salient in the current debates on law and liberal democratic institutional arrangements. The first is posed by concerns with the principle of equality, both formal and actual, which results in changes in the idea of justice, legal reasoning, forms of law and the concept of rights. The second issue is the growing differentiation of law because of its adaptation to the complex and pluralistic, modern democratic society and efforts to include local experiences of collective actors, defined as minorities, in interpreting universal legal standards and principles. Third is the issue of the deeper justification of law, and of the interpretation of rights that could be binding for democratic legislation and law application, similar to how the doctrine of natural law justified the law in the early modern times. Finally, there appear concerns about the 'bottom up' and 'from above' processes of lawmaking, on the possible 'democratic deficit' in the supranational or a local lawmaking, and the overlapping legal systems in the contemporary world. Such concerns are awakened by the new modes of participation in legislation in form of deliberations between many governmental and nongovernmental bodies, and the state- and nonstate actors within the complex system of governance.

One of the main questions raised in modern debates on liberal democracy concerns the concepts of equality and justice – no longer defined in formal, but in substantive terms such as protection of equal opportunity and positive discrimination based on the idea of equal participation guaranteed every citizen by the democratic state. Initially debates on social justice and equal participation in public life, and the role of the state in their protection, pointed to the growing scope and range of state intervention and its consequences for law, on the one hand, and the civic engagement of the democratic electorate on the other. These are especially vivid with regard to the welfare state and concern policy-oriented legal reasoning based on an emphasis upon broad standards of fairness and the social responsibility of the state.

It is argued that the political organization of the democratic welfare state challenges the universality and autonomy of the law, as well as its democratic legitimacy. The law becomes an instrument of state intervention, characterized by a growing number of particular entitlements to definite substantive goals. Authors, such as Niklas Luhmann in Germany, have pointed to the specific consequences for democracy and law as a result of state interventionism. According to Luhmann, political inclusion – i.e., the subordination of an ever-growing range of social relations to the intervention of the political democratic system of the welfare state – imposes new public tasks on the state, which is considered responsible for the well-being and quality of life of its citizens. This results in rising social demands for new standards and new regulations of ever broader and more particular issues, from minimum wage, to the functioning of kindergartens, to the regulation of public places not in the form of citizens' rights, but citizens' claims on the state (Luhmann, 1981: 38–40).

This phenomenon is described as the 'socialization of the law,' on the one hand, and 'juridification' or 'legalization' of social relations on the other, that result from the claims of the democratic electorate directed on state law. These new developments lead to changes in the form of legal regulation and legal intervention, and of relations among the legislative, judicial, and executive branches. The integrity and autonomy of the legal system is challenged by increasingly specific demands for interventionist legal regulation and the necessity of ad hoc reactions to changing social needs. The 'flood' of changing legal regulations comes to be characteristic of interventionist state activity that transform social needs into claims on the state. Moreover, instrumental legislation is produced to an ever-increasing extent

by governmental executive agencies – and not by the democratic legislature – in the form of administrative prescriptions. The reasons for such instrumental regulations are given as concerns for technical efficiency and economic effectivity, in the fulfilling of state tasks: thus, the technical standards on which the regulations are justified strongly limits the public debate on the contents of the law, possibly resulting in the growing passivity of a democratic electorate. Therefore, the legitimacy of the modern, instrumental law depends in an ever-greater degree on the efficiency of the interventionist state. Therefore, not only growing demands for social justice, transformed into ever more particular claims on the state but also the limited public debate present serious challenges to the relationship between law and democracy.

The demands for social justice, characteristic of modern democracy, are presently not only taking the institutional form of interventionist legislation. They are to an ever more visible degree characterized by the stress on the nondiscrimination, and the equal participation principle. Classic liberal approaches to the principles of equality and equal treatment are challenged by citizens for whom formal equal treatment is not acceptable, because of the specific and differentiated social experiences, specific lifeworlds that require particular attention from law. These issues were initially raised by feminist jurisprudence, and also by critical race scholars and critical legal scholars. Equality cannot be reduced to sameness, writes a representative of the feminist critique of law, arguing for accommodation of women experiences into law and policy (Fletcher, 2002: 149).

Thus, according to the feminist critique of liberal law, western liberal legal systems "… reflect the characteristics of their predominantly male architects: the legislators and judges" (Barnett, 1998: 9). In effect, in a liberal democratic society "… the opinion of the majority is precisely what underpins the sexism and inequality which women have traditionally suffered and continue to experience, despite the many formal legal reforms" (Barnett, 1998: 106). More precisely, the feminist critique of liberal law is directed against its 'objectivism' and formalism, its lack of sensitivity to the specific lifeworlds and experiences of women, and also against the dominant, i.e., hegemonic legal discourse, characterized by the conceptualization and interpretation of rights imposed by the male-dominated legislatures and judiciary.

The struggle to incorporate into democratic legislation greater equality, differentiated experiences, sensitivities, and abilities, as well as different worldviews and discourses, has already resulted in the introduction of new institutional arrangements: new standards and principles in form of the quotas regulating the representation of women in the lawmaking bodies, above all in the parliaments, in the redefinition of crimes and procedural rules, in the introduction of new standards and reasons for regulations on pornography, prostitution, or sexual harassment. The reasons on which legislation and law interpretation is based shall express women's experiences, their possible suffering, in order to change the regulations and law application in a democratic, but nevertheless male dominated, society. The new regulations on participation in democratic legislation are based on the concept of empowerment of those who were actually, and not necessarily formally, excluded from the public sphere, like women, racial and ethnic, or religious minorities. These new legal standards and regulations indicate a process of the deepening and broadening of liberal democracy, the reconceptualization of the democratic rule of law principle, and rethinking of the legitimization issue that result from the growing sense of subjectivity by those, whose voice was difficult to hear in the public debate. This, in turn, further leads to the differentiation of legal standards and regulations, and the growing complexity of law in contemporary liberal democracies.

The increasingly more technical legal reasoning, as well as the growing differentiation and complexity of legal standards, and the increasing importance of the executive branch of government are subjects of deep concern with regard to the democratic legitimacy of law and its binding force. There appears a question about the deeper justification of law and the interpretation of legal rule that would be able to encompass different lifeworlds, experiences, lifestyles. Thus, in late-modern democratic society, there are demands for the interpretation of law to be more reflexive, and context sensitive, in order to create a nonfictive 'living law' responding not only to rapid social change, but to social differentiation and the growing public awareness of rights. It is noted that such concepts and principles as the rule of law, human dignity protection, the division of powers, human rights, and definitions of citizenship are far from clear cut, and are not even clearly defined by the law itself. On the other hand, however, they have great symbolic value and, as such, they respond to gaps or inadequacies in the law.

The demands for 'reflexive law' in democratic society are strongly supported by social philosophers who advocate a procedural and communicative rationality-based approach to law, especially constitutional law (Habermas, 1993), and by lawyers who argue that new forms of law are characteristic of the contemporary world. According to these authors, in the globalizing world the constitution of the global social systems relates the law to the particular systems (e.g., economic, scientific, or religious) at issue. Therefore, in line with some arguments raised by Niklas Luhmann, here the constitution is examined in terms of structural coupling between law and another social subsystem as the constitutional object (or the social field the law regulates) (Teubner, 2004a,b, 2012). Such propositions are supported by political scientists, who argue that democracy itself is changing in the contemporary world. Instead of classical arrangements of liberal and majoritarian democracy, new forms of government emerge that include public participation in form of deliberations and engagement of nongovernmental organizations (NGOs), half-private, half-public actors, associations of citizens, employers, and employees in the lawmaking procedures. Another important feature of late modernity is the impact on lawmaking of lobbying groups, NGOs, or spontaneous social movements representing civil society. These new developments seem to be both inevitable and benign, but the issue arises as to how a social contract is possible if one considers the pluralism of values and lifestyles and the increasing differentiation of collective interests characteristic of late modernity. One may plausibly argue that these phenomena, and the struggle of collective interests (e.g., in the form of lobbying for particular legislation) could have a deteriorating effect on the democratic legislature and would put in question the legitimacy of law.

In an attempt to answer the question of legitimacy Jürgen Habermas postulates the discursive and procedural legitimacy of legal and political institutions, which are to be justified not in common values, but in procedures regulating free and unconstrained public debate on values and norms, open to every citizen at any time (Habermas, 1986, 1993). According to this view, only those norms can be considered justified that would stand up to unlimited and unrestricted debate. The stress is placed here on engagement in the public debate of civil society – a necessary link between the private and public sphere – that answers contemporary demands for interpretation of law close to local experiences, and the equal application of universal legal standards. Only then the law as well as democratic institutional arrangements have a chance to recover their institutional background. According to such arguments, civil society and public debate create a strong connection between the democratic political system and the system of law. Public debate imports local meanings and values, and particular experiences into interpretations of general and universal legal principles. However, it leaves open the issue of when compromise is impossible. A prerequisite for the functioning of such a model of procedural and discursive democracy is the revival of virtues, of the republican spirit, or habits of the heart characteristic of civil society, which make citizens participate and present their arguments, but also tolerate arguments presented by others. Within this model, proceduralization also means a growing stress on the role of the constitutional court regarding its relation to the political legislative process, and its activity as key in the formation of democratic will. Hence, the fundamental principles of democratic liberal constitution and constitutional control of political process are the important institutional arrangements that are able to control and tame the conflicting interests when consensus is not possible. Hence, one speaks about the constitutionalization of the political process in contemporary liberal democracies.

On the other hand, however, the new forms of government, known as *governance*, obviously have a great importance for current conceptualizations of law and its legitimacy. Legitimacy is given as the result of bi- and multilateral deliberations of various stakeholders, and reflects a consensus or a compromise among the various interests at stake. These new developments question not only the democratic legitimacy of law in the classical sense, but also the capacity of law to control and tame the struggle of the interests of actors engaged in the deliberations, and to protect the public good as well as citizens' rights. These new developments further contribute to the growing importance of judicial review – above all, of constitutional review – as not only controlling the application of law in individual cases, but also as controlling the conformity of governmental decisions and parliamentary legislation with the constitution. Instead of a clear separation of powers, a functional interdependence of the legislative, judicial, and executive branches of government characterizes modern democracies.

The model of procedural democracy and the proceduralization of law leaves some questions open. In light of this model's propositions, the legal and political systems of modern democratic societies are not only flexible but also fragile, their institutional arrangements and interpretations of norms depend on the results of debates and deliberations, or are left unresolved because common understanding or compromise cannot be reached. Here two questions emerge: (1) about stable and reliable foundations for the adjudication and legitimation of the democratic state ruled by law, and (2) about constraints on political and judicial deliberations.

In contemporary democracies, stable foundations for the legal as well as political system are sought in the concept of rights. This increasingly important approach to law – called 'new personalism' (Friedman, 1990: 44–46) – refers to inalienable human rights as a higher standard for evaluation of democratic and legal system functioning. This would serve as a final test according to which the quality of democratic and legal order would be measured. Therefore, the relationship between democracy and law in modern, complex, and pluralistic societies must be analyzed and evaluated with reference to universal standards – encompassed by human rights – interpreted and applied in the changing social and differentiated cultural conditions of the modern world. Protection of human rights presents also the most important constraints to political decision making and law application.

The Contribution of the Experience of Authoritarian and Totalitarian Regimes to the Democracy and Law Debate

The recent peaceful revolutions in Central and Eastern Europe were also called 'lawful' revolutions, since the observance of law, and the establishment of the rule of law was on the agenda of democratic dissent in that part of the world. However, the democratization process following the collapse of authoritarian and totalitarian regimes not only in Europe but also in Latin America, and most recently in Egypt or Tunisia, raised some fundamentally important legal issues, or reawoke some debates highly relevant for the analysis of the relationship between democracy and law.

Especially in Europe and Latin America, it was the important issue of inalienable human rights, and the idea of laws that are higher then man-made, positive law and therefore cannot be changed by regular, democratic procedures. Second, was an issue of control of the democratic legislature, i.e., the place and role of judicial review, constitutional review, and the review of supranational courts and tribunals (of which the European Tribunal of Human Rights presents a model example) of the democratic lawmaking process. Third, the issue was raised of 'transitional justice' i.e., of settling accounts with past human rights violations, to deal with the complicated legal matters and to invent procedures and institutions that would help to restore the sense of law and justice in these societies.

In Europe, the abuse of legality by Nazi, fascist, and communist regimes necessitated a new, rights-centered concept of legality and the rule of law. The issue of fundamental human rights as a higher legal order to which the positive law must subordinate itself was famously raised by the necessity of new constitutions in societies on the path to democratic reconstruction. The example was set by the German Basic Law of 1949 which – in its opening Article One – refers to the principle of inalienable human dignity and human rights, which are directly binding, and which are fundamental for every human community, for peace and justice in the world. The next 20 articles of that Basic Law that declare human rights and

liberties protection are pronounced inalienable. The issue of human rights was on the agenda of all dissident movements in the East Central Europe, and elsewhere. One speaks about the human rights revolution on a global scale, which had its roots in the 1948 Universal Declaration of Human Rights, the 1950 European Convention of Human Rights, and the international conventions of the 1960s – the International Covenant on Civil and Political Rights, and the International Convention on Economic, Social, and Cultural Rights. These conventions within a framework of the Helsinki peace process proved to be of salient importance for democratic dissent. As the source of human rights, and of human dignity, the classical concept of natural law has been evoked, again first in the German Federal Republic after World War II. Later this concept was referred to in East Central Europe. However, the revival of natural law as the source of human dignity and human rights opened a new set of questions and challenging issues in the debate on law and democracy. Among them the most salient follow who has the legitimacy of natural law principles interpretation, the interpretation of the human dignity principle and of human rights content in the modern, complex, pluralistic, and democratic society. This question concerns the concept of justiciable human rights substantively, and the specific mechanisms and institutional devices for safeguarding them, in the system of democratic government.

This put on the agenda again the issue of the judicial control of democratic lawmaking, and the place of the judiciary within the democratic political system. One speaks about the 'judicialization of politics,' or 'global expansion of judicial power' (Tate and Vallinder, 1995). According to Said Arjomand, one important consequence of political reconstruction presents the judicial activism (Arjomand, 2003: 8). This phenomenon is characteristic of the so-called era of 'new constitutionalism' since 1989 that is "marked by a mixture of increasingly judicialized legislation by parliaments and administrative organs and legislative jurisprudence by constitutional courts and supranational judiciary organs" (Arjomand, 2003: 9). As had been stressed with regard to post-Nazi Germany and postcommunist Eastern Europe, as well as in postauthoritarian Southern Europe and elsewhere, constitutional courts and tribunals with rights jurisdiction built into them, in some cases also the institution of an ombudsperson play a key role in the transition to democracy and protection of the rule of law centered on human rights protection, as guardians of the liberal democratic constitution (Bryde, 1999: 28–29). This puts in question the classical separation of powers in liberal democratic regimes (Stone Sweet, 2000: 139–152).

Finally, one has to reckon with past legacies and expose the truth about the former regime. At stake is the principle of the law-governed state, interpreted under conditions of mass-scale human right violations committed by the former regime. Thus, the term transitional justice was invoked and interpreted as a period of time when the former perpetrators of atrocities and their accomplices are put on trial (Teitel, 2000).

There are important contributions to the debate on democracy and law, as well as to the very concept of the rule of law resulting from posttotalitarian and postauthoritarian experiences with 'transitional justice.' These take form of new rights among which the 'right to truth,' to compensation of losses and restitution of rights presents their crucial, institutional crystallizations.

A prominent lawyer, the Executive Director of the Inter-American Institute on Human Rights in Latin America, argues that facing and reckoning past human rights abuse constitutes an obligation for new governments. They need to investigate, prosecute, and punish; they also need to disclose to the victims and society all that can be reliably discovered about the circumstances of such crimes, including the identity of the perpetrators and instigators. Such an obligation is translated into a society's right to truth (Mendez, 2009: 39). This right emerged in an age of gross violations of human rights, giving rise to high numbers of perpetrators, instigators and collaborators, and victims, and was formulated to deal with an unprecedented technical capacity of hiding the truth. Thus, the right to truth comprises a civic right of a new type, a response by a civic society to the increasing possibilities of concealing atrocities, destroying evidence, and silencing people – behavior typical of modern dictatorships and totalitarian regimes. As such, it is a most important contribution to interpretation of the law-governed state principle after the collapse of a totalitarian or dictatorial regime.

The right to truth is based on a belief that the truth about the past, if disclosed and disseminated, brings both restitution of dignity to victims and retribution for the past atrocities. In East Central Europe, such an obligation stems from the conviction that 'living within the truth' is a crucial part of the moral capital with which these societies initiated their transformation toward democracy. If taken seriously, the right to truth serves as crucial guidance in the process of differentiation of the new political system from the previous one. Therefore, the truth about the past is constitutive for new democracies. It contributes to the restoration of victims' dignity and the protection of their rights. It also comprises an initial step in the process of public enlightenment, of public self-reflection, as well as differentiation from the past.

Moreover, the right to truth represents a specific form of the broader civic right to information enshrined in every democratic liberal constitution. Further, the right to truth is directly and imminently connected with another one: the right to remembrance and to present one's own experiences, contributing to the collective memory in a democratic society. The right to remembrance places democratic governments under an obligation to document the particular experiences of individuals and broaden the official version of national history by local experiences. Wrongs must be documented, evidence collected, and the 'white spots' of a nation's history filled in order to render the collective memory more democratic and, above all, include the memories of victims. In order to meet this obligation and protect the right to remembrance, new 'institutes of national remembrance,' or similar institutions, have been established. If protected, these rights to truth and to remembrance contribute to the process, which could be labeled 'public enlightenment.'

Interestingly, it is the civil society, whose struggles against policies of past concealment contribute to this process of public enlightenment and large-scale public learning, thus guaranteeing protection of the right to truth and to remembrance. As already witnessed during global processes of reckoning with the past, the quantum of victimization has seldom been exposed by governmental or international bodies (Bassiouni, 1996: 11). Likewise in Eastern Europe that task has primarily been undertaken, with all its understandable limitations, by NGOs

such as Charter 77 in Czechoslovakia, or the Committee for the Defense of Workers of the late 1970s and early 1980s in Poland, or the Memorial organization in Russia thanks to which we learn about atrocities committed by the USSR. There are also organizations of victims of the tyrannical regimes, of slaves condemned to work in Siberian or other labor camps, of owners deprived of their property, of mothers, of dedicated journalists, and of committed researchers struggling to expose the truth and not forget it.

However, there are great dilemmas and important ambiguities to reckon too. One must be aware that democracy is open and vulnerable: open to any organized interests, and therefore vulnerable because these could be antidemocratic and/or even represent those who played a crucial role in the functioning of the previous system. One has also to acknowledge the fact that past reckoning brings much temptation to the new, democratic governments. It is a temptation to get rid of political opponents, if only one can find any evidence, however feeble, that they collaborated in the functioning of the former regime. Therefore, it is important that the past-reckoning activities be subordinated to transparent procedures. In this respect, the role of courts, especially of constitutional courts, has been stressed (Solyom, 2003: 133–161).

Conclusions

In the contemporary world, the relationship between law and democracy is increasingly problematic in all relevant dimensions: democratic participation in legislation, social and political subordination to law, and legal control of democratic majority, here called the taming of democracy by law, in order to protect rights and liberties of citizens. The contemporary challenges have been answered by new developments characteristic of law, that, in turn, result not only in the growing controlling power of the judiciary but also in the empowerment of citizens. The latter takes the form of the broad interpretation of the nondiscrimination principle and the protection of individual, and recently also collective, rights. Therefore one can speak about broadening and deepening democracy, accompanied by the parallel growing importance of rights. These new developments have been enhanced by the collapse of authoritarian and totalitarian regimes in Europe and elsewhere. However, one observes new phenomena consisting in the growing importance of sub- and international processes, presenting new challenges to both democracy and law and resulting in the fragmentation of relations between them. Therefore, the relationship between law and democracy in the contemporary world needs further deep attention and analysis.

Law and Development

David M Trubek, University of Wisconsin–Madison, Brooklyn, NY, USA

Abstract

'Law and development' refers both to organized efforts to transform legal systems in developing countries to foster economic, political, and social development and to the academic projects stimulated by these efforts. Begun in the mid-twentieth century, law and development's dominant ideas and projects have changed over time as theories of development and agency priorities have changed. Law and development efforts accelerated in the 1990s as international financial institutions began to emphasize the rule of law. As the twenty-first century dawned, ideas and projects of the twentieth century were assessed and critiqued, new themes emerged, the field fragmented, and consensus disappeared.

Law and development refers to organized efforts to transform legal systems in developing countries to foster economic, political, and social development. The term also refers to the academic projects associated with these efforts. Begun in the mid-twentieth century, law and development's dominant ideas and projects have changed over time as theories of development and development agency priorities have changed. Twice in the twentieth century, a consensus formed and guided practice. As the twenty-first century dawned, ideas and projects of the twentieth century were assessed and critiqued, new themes emerged, the field fragmented, and consensus disappeared.

In the twentieth century, law and development focused on the use of domestic law as a tool to facilitate economic growth, and priority was given to law as an instrument to empower developmental states. Toward the end of that century, this approach gave way to a focus on law as the underpinning of markets and a restraint on the state (Trubek and Santos, 2006).

In the twenty-first century, new ideas and forces are once again transforming the field. The increasing impact of global forces has drawn more attention to the role of global institutions and actors, new ideas about how development works have led to calls for more use of law as a framework for public–private coordination and experimentation, and interest in law as an element of development itself has led to stress on guarantees of basic rights. Finally, recognition that much twentieth-century law and development effort was based on weak or faulty knowledge (about both the role of law and the possibilities for reform) led to calls for more research, an evidence-based approach to planned change, and horizontal learning among developing nations.

Law and Development in the Twentieth Century: Domestic Law and Economic Growth

The idea that a nation's legal system affects its economic and social prospects can be traced back as far as the eighteenth century. In the nineteenth century, German sociologist Max Weber argued that European legal systems were an important factor in the development of capitalism (Trubek, 1972). But it was only in the twentieth century that governments and international institutions concerned with development began to organize systematic legal reform projects. The 1960s saw the start of support for legal reform efforts by international development agencies and the beginnings of academic study of law and development. By the late 1970s, agency interest had waned and the academic enterprise stagnated. However, in the 1980s, new ideas about law's role in development began to emerge. This spurred increasing interest by development agencies; the pace of support for systemic reform picked up, and academic study revived (Davis and Trebilcock, 2008). International development agencies spent billions on legal reform, and scholars in several disciplines other than law began to study the role of law in development.

The second half of the twentieth century saw the emergence of various theories and approaches. The focus was on domestic legal systems, and the goal was increasing economic growth. Three major themes can be identified, and they are discussed in this section.

Law Can Be an Instrument to Be Used by Developmental States to Foster Change

The first law and development movement stressed the need for change in economic and social relations and expressed hope that new laws could induce such change. This body of thought drew on modernization theory and the view – widely held by economists around midcentury – that a strong state was needed to manage the economy and transform society (Thomas, 2006). Law, in this view, could serve as a positive instrument of change. Law could increase state capacity. It could offer incentives for people and institutions that are 'modern' and would promote growth. It could create disincentives for those who resist change and cling to traditional values (Davis and Trebilcock, 2008). In what Trubek and Santos (2006) call the 'first moment' of law and development, there was a consensus on the importance of the state and the need for modernization, and this consensus helped structure a development policy that focused on the use of law to strengthen the state and transform society.

Law May Be a Barrier to Economic Development

From the beginning, even those who had a positive view of law understood that the wrong kind of legal rules and practices could reduce incentives for investment and increase the cost of innovation. Concern about the negative impact of law grew in

importance toward the end of the century as development agencies lost faith in state intervention and began to put more stress on the role of markets and on the need for deregulation (Kennedy, 2006).

Law Should Be a Framework to Facilitate Private Decision Making

As development economics turned away from a belief in state-led initiatives, more and more emphasis was placed on the role of law as a framework within which private actors would make economic decisions. In the second 'moment' of law and development, a consensus formed that priority should be placed on the role of law as the underpinning of markets and a means of restraining excessive state intervention. This new consensus guided reform efforts in the 1990s and beyond. Scholars stressed that, to function properly, markets require a complex infrastructure of institutions and rules, including legal rules such as the laws of contract and property (North, 1991; Dam, 2006; Trebilcock and Daniels, 2008). They also recognized the importance of qualified legal professionals and judges in ensuring that the laws are effective (Trebilcock and Daniels, 2008). Markets may also require regulations, like antitrust and securities law (Dam, 2006; Trebilcock and Daniels, 2008). Much of the interest in legal transplants and in judicial reform for development, which made up the bulk of international support for law reform in the late twentieth century, was based on the importance of creating such a 'neutral' framework.

The Mixed Legacy of the Twentieth Century

The legacy of the twentieth century is a complex one. First, the hoped-for academic field of law and development never materialized. In 1974, Trubek and Galanter (1974) criticized scholars' excessive closeness to development agencies and called for greater academic detachment. This article, intended by its authors to strengthen the field, ironically helped bring about its demise by questioning core assumptions and weakening the link between funding agencies and the academic world. For a decade or more, scholarly work on law and development declined. But, by the late 1980s, academic interest increased and several other disciplines, including economics, took up the topic. However, nothing like a 'field' took shape. While the number of studies and publications grew exponentially, there still is no association that brings law and development scholars and practitioners together, no agreement on canonical texts, and no publication that is widely read and commands broad respect. Brian Tamahana (2011) argues that such a field is neither possible nor desirable, while others hope for greater coordination and integration of knowledge in the future.

Second, the experience of reform was mixed as best: some projects failed, and some transplanted laws did not 'take.' Some decided the whole enterprise was fundamentally flawed and that organized efforts by external actors to promote legal reform were doomed to fail. They argued that it was impossible for external actors to understand how developing countries' legal systems work and/or to craft workable reform strategies (Tamahana, 2011). Others were more sanguine: they believed that law could matter and that properly planned reforms could have an effect. But they admitted that the empirical base for reform was too thin and called for more research to identify what works and what does not (Davis and Trebilcock, 2008).

Third, conflicts arose among the several ideas that dominated the period. There are tensions between the idea of the use of law by a strong developmental state, on the one hand, and a deregulatory push, on the other; between law as an instrument to change behavior and law as a neutral framework; and between deregulation and the need to create new institutions (Kennedy, 2006). Law and development scholars had trouble incorporating the lessons of the East Asian miracle: while countries like Taiwan and Korea experienced rapid and inclusive growth, their legal systems did not conform to the precepts of the law and development orthodoxy of the 1990s (Ohnesorge, 2006; Jayasuriya, 1999).

Finally, lawyers and economists diverged in their views about methodology, their interpretation of data, and the policies they derived from the data. One of the most important changes in law and development in the twentieth century was the discovery of the field by economists. The economics profession paid scant attention to law in the 1960s and 1970s, but starting in the 1980s development economists began to take law seriously. This led to a series of studies, including several about the importance of law in the creation of financial markets. One series widely discussed were the studies purporting to show that legal systems whose origins were in the common law were superior for financial development than those based on the civil law (La Porta et al., 1998, 2008). Lawyers found these studies less than persuasive, pointing out numerous flaws in the reasoning employed and suggesting the need for alternative approaches. In a very influential article, legal scholar Katherina Pistor showed that some of the studies used simple models that presume that lightly regulated markets are optimal, fail to capture the complexity of real legal systems and the normative choices they encode, misunderstand the relationship between the history of a legal system and its ability to incorporate specific rules, and rely on questionable assumptions about causal relations between law and economic outcomes. Rejecting the methods used in such studies, she prefers an approach partially inspired by comparative law and sociolegal studies (Pistor, 2009). All these issues and many others continue to be debated in the academy and in practice (Davis and Trebilcock, 2008).

Law and Development in the Twenty-First Century: Continuity and Change

Thus, as the twenty-first century dawned, law and development was faced with unresolved issues and unfinished tasks. Leading scholars looked for lessons to be derived from the expansion of reform efforts in the 1990s and early 2000s, tried to reconcile tensions among the different ideas about law and about development in the twentieth century, started to deal with new trends and phenomena, and called for the creation of a systematic body of knowledge that could serve as a reliable guide to reform efforts (Davis and Trebilcock, 2008; Trubek and Santos, 2006). Others suggested it would be best to give the whole thing up as a bad job (Tamahana, 2011). For those who felt that law could

make a difference in development, and who believed that externally supported reform might still be desirable, there was a lot of experience to digest as well as new ideas to incorporate and new challenges to face.

Evaluating the Experience of the Twentieth Century

Much of the literature in the early twenty-first century focused on the experiences of the prior decades, codifying what was known, pointing to gaps in knowledge, and critiquing assumptions behind theories and policies. Between 2002 and 2011, at least seven important books on law and development in general, along with numerous specialized studies, were published in the United States alone. Some of the general studies looked at past reform efforts (Jansen and Heller, 2003; Carothers, 2003) and underscored the limitations of knowledge about law and development and the obstacles to effective reform, including the difficulties of transplanting legal institutions from one country to another. Others offered an overview of the legal reforms needed for capitalist growth and summarized the state of knowledge accumulated in the twentieth century about specific areas of law and key legal institutions (Dam, 2006; Trebilcock and Daniels, 2008; Trebilcock and Prado, 2011). These studies looked at the role that could be played by reforms in private law, regulation, criminal justice, the role of the judiciary, legal education, and the legal profession and summarized what was known about reforms that had been carried out in these areas. The literature included a critical strand: Dezalay and Garth (2002) placed law and development within the context of global forces and the hegemony of neoliberal development economics, while authors in the volume edited by Trubek and Santos (2006) outlined several critiques of mainstream twentieth-century law and development policies and practices. They noted that the supposedly neutral framework of private law could favor certain groups over others and affect the distribution of income. They also contended that the reform effort of the 1990s had favored economic goals over social protection and inclusion.

New Ideas, New Forces, New Institutions

The new century also saw the emergence of new ideas in development economics, new forms of state activism, and new issues for the field of law and development. New approaches to development economics and the emergence of new kinds of developmental states required new ideas about the role of law. Trubek et al. (2013) produced a study of the revival of industrial policy and other new forms of state activism in Brazil and suggested that these new strategies called for yet another reassessment of law's role in development. Global forces, including international economic law, began to play a greater role in the shaping of domestic legal systems. And there were calls to go beyond the instrumental view of law as a tool for development and treat a functioning legal system with basic guarantees as an element of what should properly be called 'development.' Law and development scholars recognized the limits of their knowledge and called for more empirical research, while the capacity for such work by scholars in the Global South began to expand.

Law Should Facilitate Experimentation and Innovation

By and large, twentieth-century law and development experts assumed that the path to development was known and the challenge was to create instruments and institutions that would help move nations down that path. For those who saw law as an instrument of state control, knowledge about the path forward would be provided by state planners, and the law would implement the plan. Those who rejected planning thought that unrestricted markets would make the optimal economic choices, so the right way to foster development was to create markets and leave them alone (Trubek et al., 2013).

However, in the twenty-first century, many are coming to believe that neither planners nor markets working alone can find the optimal path. Rather, strategies must evolve and investment choices must be made through public–private partnerships and processes of iterative experimentation (Rodrik, 2004; Sabel, 2007; Sabel and Reddy, 2003; Hausmann et al., 2007). These processes require new forms of governance and law. In such an 'experimentalist' developmental state, law can be neither a simple tool for direct state invention nor merely a neutral framework for private decisions (Pires, 2008). Rather, the law should seek to establish partnerships between public and private sectors and institutionalize a process of mutual search for innovative solutions and optimal developmental paths (Trubek et al., 2012).

Law Is Increasingly Affected by Global Forces

Twenty-first century law and development must deal with the growing impact of global forces on the law (Dezalay and Garth, 2002; Trubek et al., 1994). There are three major forces at work. The first is the availability of global models such as the formulae for law and development promoted by the World Bank (Davis, 2004; Davis and Kruse, 2007; Santos, 2009). Whether or not a country receives funding from the Bank, the models it promotes have an influence on national thinking. Second, national lawmakers must take account of the role that law plays in determining national competitiveness. The more a country's development strategy depends on foreign investment, the more its laws will be subject to scrutiny by foreign investors, who will compare the legal environment for development in various nations before deciding where to invest. Today, investors have many options and law becomes an important factor in the effort to attract capital. The third global force is the growth of transnational law. Increasingly, a nation's legal order is affected by norms originating outside of its borders. Whether they are norms of regional bodies (like the North American Free Trade Agreement or Mercosur) or of global institutions like the World Trade Organization, national legal orders are subject to constraints from higher levels of governance (Trachtman and Thomas, 2009; Shaffer et al., 2008; Santos, 2012).

Law Itself Is Part of Development

All the major ideas about law and development in the twentieth century saw law as a *means* to some other goal, whether economic growth or social protection. But recently, scholars have argued that the existence of the 'rule of law' is a goal in itself, a necessary part of the process of empowerment and capability enhancement that constitutes 'development' (Sen, 1999). This

means that legal protection for constitutional values and human rights, including economic and social rights, must form part of the law and development agenda along with economic law and judicial reform (Sen, 1999; Rittich, 2004).

Recognition of the Need for Evidence-Based Policies

As more evidence about the failures of twentieth-century reform efforts accumulates, there are increasing calls to get beyond abstract debates and develop empirical evidence concerning what works and what doesn't work (Carothers, 2003; Jansen and Heller, 2003; Davis and Trebilcock, 2008). There is very little empirical work of any kind on the role of law in developing countries, yet the whole law and development enterprise requires such knowledge. That will include developing tools to diagnose problems and measure the results of reforms. The creation of cross-country legal indicators by agencies like the World Bank is a reflection of the search for such tools. But this process is still in its infancy, and there are questions about some of the indices being used and the policies derived from them (Davis, 2004; Davis and Kruse, 2007). Indicators can be misleading if they rely on only the formal written law, not the law as it is actually applied, or are drawn from user surveys that are not truly representative (Santos, 2009). Moreover, even when the data reflected in the indicator are accurate, sometimes policy makers make questionable leaps from the data by proposing reforms that are either inappropriate or beyond the capacity of the government to carry out.

Increasing Law and Development Capacity in the Global South

Developing countries need to make a quantum leap in their capacity for sociolegal research. One of the most important developments in recent years is the growth of law and development capacity in the Global South. While scholars in developing countries have always been aware of the role that law might play in development, their capacity to study and analyze these issues has been limited. Law and development calls for an interdisciplinary approach and demands empirical research. The legal academies in much of the Global South were ill equipped for such work. They did little systematic research and what was done was largely doctrinal. Toward the end of the twentieth century, this began to change: legal scholars in some countries acquired interdisciplinary knowledge and empirical skills, law schools supported research and teaching on development issues, and some funds for empirical research became available. Legal scholars from some developing countries began to exchange ideas and share experiences: for example, in 2010, scholars from Brazil, Russia, India, and China met in São Paulo to discuss selected law and development topics (Schapiro and Trubek, 2012). As capacity grows, and as more cooperation between the legal scholars of developing countries occurs, 'law and development' may be institutionalized in the Global South and the kind of 'horizontal learning' among developing nations illustrated by the São Paulo meeting may increase.

Conclusion: Fragmentation and an Uncertain Future

While reform continues and academic work on the role of law in development is expanding in the Global North and the Global South, there is no consensus on the nature of the challenges or the appropriate policies to follow. Twice in the history of law and development, a dominant law and development paradigm emerged, which served as a guide to policy makers (Trubek and Santos, 2006). But today the 'field' is fragmented in many different ways. While there is more academic work than ever, no approach is dominant and no policy consensus can be found. A review of the current debates suggests fragmentation along three axes. The first is the basic approach that scholars take to the law and development project itself. The second is disciplinary, with economists and lawyers often looking at similar issues but using different methods and reaching differing conclusions. The third is substantive: while work on law and development once brought together all relevant topic areas, today these issues are often taken up in separate academic silos with little communication among them.

Attitudes toward the Project: Skeptics, Critics, and Optimists

In a masterful review of the recent academic literature, Kevin Davis and Michael Trebilcock (2008) divided the field into skeptics who have serious doubts about the project and optimists who recognize problems but remain hopeful about the enterprise. In fact, the field seems to be divided among *three* groups that take very different approaches to the whole idea of externally supported legal reform as a tool for development. The first are the skeptics who believe that either law does not matter for development or, if it does, the external actors are incapable of understanding what is needed and will always get it wrong (Tamahana, 2011). The second are the critics: they know that law matters. They think that external actors know what they are doing and the reforms they promote serve identifiable aims. The problem, say the critics, is not with the effectiveness of the norms but with who loses and who benefits from them. For example, some see external reforms working, but in a way that may weaken social protections and benefit global capital (Rittich, 2004). Finally, the optimists believe that law matters, that legal reforms can be crafted that will benefit all in developing societies, and that external agencies, properly guided by empirically informed research, can make a difference (Davis and Trebilcock, 2008).

Disciplinary Divide

The division between lawyers and economists that started in the twentieth century has continued. Thus, when leading proponents of the 'legal origins literature' restated their position concerning the superiority of countries that adopted the common law (La Porta et al., 2008), legal scholars, including Katerina Pistor and John Ohnesorge, expanded the critique of the methods used and conclusions reached by the economists (Pistor, 2009; Ohnesorge, 2009).

Topical Fragmentation

A final source of fragmentation can best be described as topical. As interest in development grew, various legal disciplines began to explore the relevance of their topic for development broadly defined. Thus, we saw the growth of interest in trade and

development, finance and development, human rights and development, women's rights and development, and so on. While these topical specializations enriched our knowledge of the prospects and pitfalls of law in development, they often became independent specializations in themselves, thus contributing to further fragmentation of the field.

An Uncertain Future

Academic interest in law and development in the Global North has never been stronger, and capacity in the Global South has grown. These developments promise to provide insights that will influence reform. Yet the proliferation of studies and the fragmentation of the field along multiple axes suggest that we may never see the emergence of another dominant paradigm like those 'moments' that existed in the past.

Abstract

Economic analysis of law is concerned with (a) determination of the effects of legal rules and (b) evaluation of the desirability of the effects of legal rules, with respect to well-specified definitions of social welfare. This article surveys the approach as it applies to basic areas of law – accident, property, contract, and criminal law – as well as to the litigation process. The economic approach is also contrasted with traditional analysis of law, under which the effects of legal rules are not usually systematically assessed.

Under the economic approach to the analysis of law, two basic questions about legal rules are addressed: descriptive questions, concerning the effects of legal rules on behavior and outcomes; and evaluative questions, concerning the social desirability of the effects of legal rules. In answering these questions, the method employed is that used in economic analysis generally. Namely, individuals and firms are ordinarily presumed to be forward-looking and rational, and the framework of welfare economics is adopted to assess the social desirability of outcomes. The field of economic analysis of law may be traced significantly to Bentham (1789), but lay essentially dormant until the contributions of Coase (1960), Becker (1968), Calabresi (1970), and Posner (1972). The field is now rapidly growing, although it is far from mature (one indication being lack of empirical work). To illustrate the approach, this article first focuses on accident law, briefly considers other areas of law, and concludes with a section on basic foundations and criticisms of the economic approach.

Economic Analysis of Law Illustrated: Accident Law

By accident law is meant the law governing liability for accidents, that is, the rules determining when a party who causes an accident must pay for the harm done. Economic analysis of this branch of law centers on three issues: incentives toward safety; insurance and compensation of accident victims; and litigation-related costs.

Incentives Toward Safety

A major effect of the liability system is that it fosters the taking of precautions against accidents. Suppose that a precaution will lower accident-caused harm for which a party would be liable from $3000 to $2000, that is, by $1000, but costs less than this amount, say $500. The party would then be likely to take the $500 precaution, as it would reduce the party's liability expense by $1000. Such logic underlies the conclusion that, under many forms of liability, parties will be led to take socially desirable precautions.

An important qualification about the general point that liability creates incentives toward safety applies to accidents caused by firms' products. In particular, a firm's interest in its reputation may lead it to take proper precautions even in the absence of liability. If a firm's water heaters tend to fail and consumers know about this, they will not pay as much for the heaters, and thus the firm will have a motive to reduce the risk of heater failure in order to avoid having to accept a lower price. Note, however, that this argument depends on consumers' obtaining information about product risk.

Insurance and Compensation

The role of insurance in the context of accidents and liability is of substantial importance due to the widespread ownership of insurance. A major form of insurance is liability insurance, which provides coverage against legal liability. Because liability insurers pay for much of the losses for which injurers are found liable, it might initially be thought that liability insurance largely negates the incentives toward safety inherent in liability. However, some such incentives are preserved under liability insurance because insurers often link premiums or conditions of coverage to the adequacy of precautions, raise premiums on the basis of accident history, and offer only partial coverage against liability.

In addition to liability insurance, standard insurance for victims, that is, their (private or public) medical, life, disability, and property insurance, is of significance. The prevalence of victims' insurance limits the need for the liability system as a means of assuring victims compensation for accidents.

Litigation-related Costs

The litigation-related costs of the liability system are the legal fees and associated expenses (including litigants' time and effort) borne by parties in resolving disputes that arise when harm occurs. Litigation-related costs are high; for every dollar received by a victim, it appears that over a dollar is spent delivering the dollar to the victim.

Evaluation Under the Economic Approach

Under the economic approach, the liability system is considered to be socially worthwhile where its social benefits exceed its litigation-related costs. The social benefits of the liability system do not lie significantly in compensation of victims, because standard forms of insurance for victims are a cheaper means of compensation than the liability system. Rather, the

social benefits of the liability system reside largely in its influence on accident rates. If this accident reduction effect is sufficient to outweigh litigation-related costs, the liability system is socially worthwhile. For example, the liability system might be socially worthwhile in the area of industrial pollution – perhaps the desire to avoid liability induces firms to reduce substantially polluting activity. However, the liability system might not be worthwhile in the area of automobile accidents – perhaps the prospect of liability does not affect driving behavior, which is mainly influenced by fear of personal injury in accidents.

Traditional Analysis Contrasted with Economic Analysis

The traditional view of the liability system is that its primary effect, and its major warrant for existence, is the compensation of victims of harm. This view is at odds with the economic view. On one hand, as just emphasized, compensation is to a great extent accomplished by standard forms of insurance; and, because insurance is a less expensive means of compensation than the liability system, it would be economically unwise to employ the liability system for the purpose of achieving compensation. On the other hand, the inducement of safer behavior is usually not paid serious attention under the traditional view of the liability system. Hence, the prescriptions for use of liability under the two views may conflict. Under the economic view, but ordinarily not under the traditional view, the recommendation is that the scope of liability be reduced where liability has little influence on accident frequency, and that the scope of liability be increased where liability would substantially reduce accident frequency.

A second, related aspect of the traditional view is that liability is intended to ensure the attainment of corrective justice in the classic sense that a wrongdoer should be punished by being made to pay the victim for harm done. From the economic perspective, this conception of the purpose of the liability system is problematic even in a descriptive sense. As stressed above, a party who is found liable usually does not pay a judgment himself but has his liability insurer pay; if there is punishment, it might be that the party is not fully covered or that his liability insurance premiums may rise. Hence, the degree to which a wrongdoer is punished owing to liability is not direct; it is attenuated and translated in character by liability insurance. Additionally, the victim often does not receive the payment made by the liability insurer; rather it is the victim's insurer that frequently obtains the payment (as reimbursement for the payment that the insurer made to the victim earlier). In all, then, the liability system does not achieve corrective justice in the way contemplated by traditional analysts, because they overlook the effects of liability and of victims' insurance.

Economic Analysis of Other Areas of Law

In this section, the contours of economic analysis of other major areas of law will be indicated.

Property Law

A fundamental topic in economic analysis of property law is the justification for the very existence of property rights. From the economic point of view, these rights are said to exist because they promote incentives to work, to maintain and improve things, and to trade; and, as well, because the rights reduce problems of wasteful and destructive efforts to take things and to prevent takings. Some economic literature traces historical instances of the emergence of property rights (especially in land) and certain recent property rights developments (for example, in the broadcast spectrum) to these social advantages. Property rights are seen as beneficial due to their salutary effects, not to any intrinsic belief that a person should own the fruits of his labor.

Given the general basis for the existence of property rights, many issues pertaining to property law have been addressed from the economic perspective. One concerns acquisition of property rights in things not yet owned, such as fish in the sea and undiscovered mineral deposits. Here, a theme is that the 'finders-keepers' rule has the advantage that it creates incentives to find things. Yet these incentives may be socially excessive: individuals may engage in duplicative activities to find things (a large number of fishermen may compete for fish that a smaller number could easily catch; many parties may drill oil wells, even though a small number of wells would be sufficient to extract the oil from a reservoir). When this is so, it is suggested that regulation (limiting the catch of fish, 'unitizing' ownership of an oil reservoir) may be desirable to curb the problem of excessive effort.

Another issue of interest concerns external effects associated with the use of property. These 'externalities' may be detrimental, such as pollution or noise creation, or beneficial, such as beautification of land or spraying to kill mosquitoes. Bargaining among affected parties may sometimes resolve externality problems. Suppose that a factory causes annual pollution harm of \$10 000 to its neighbor but can prevent the pollution by installing scrubbers at an annual cost of \$1000. In the absence of legal rules preventing pollution or imposing liability for it, the victim of the pollution might be expected to pay the factory to obtain scrubbers in order to avoid suffering harm. The victim should be willing to pay more than \$1000 (perhaps \$2000) for the factory to obtain scrubbers. Hence, a legal rule requiring the factory to install scrubbers, or a rule imposing liability for harm, may not be needed to achieve the result that the factory obtain scrubbers. The general possibility that externality problems may be avoided through bargaining, and that legal rules may not be necessary for their resolution, is known as the Coase Theorem, and was advanced in Coase (1960). However, much economic writing discusses reasons why bargaining may not cure externality problems: costs of bargaining (especially significant when the number of affected parties is large), breakdowns in negotiation (often arising when one side misgauges the other's situation), victims' lack of knowledge of danger (suppose the pollution is not apparent). Because bargaining will often fail to solve externality problems, attention has been paid to the use of legal rules (particularly liability rules, regulatory requirements, property rights) to accomplish their amelioration.

A very different issue in economic analysis of property law involves public property, which is to say, property like roads and libraries that the government needs to supply because the private sector will not provide them, or not in appropriate quantity. In this connection, the legal system sometimes allows the government to take land through its powers of eminent

domain, but requires it to pay compensation for its takings. According to economic analysis, the power of eminent domain may be socially desirable where government would have undue difficulty in making purchases. A standard example is that, in trying to purchase land for a road, government would be likely to be stymied by even a few landowners on the road's planned path (landowners might be tempted to hold out for strategic reasons). The requirement that government compensate for takings cannot be justified as it sometimes is, as an implicit form of insurance against takings; for, in the absence of a compensation requirement, individuals doubtlessly would purchase insurance against takings. A possible advantage of the requirement of compensation for takings is that it may discourage government from ill-advised takings, though that argument has been criticized.

Another area of property law concerns intellectual property rights: the law of patents, copyright, and trade secrets. The main theme of economic analysis of this body of law is that intellectual property rights have the beneficial effect of spurring innovations, but the detrimental effect associated with high prices and lower than socially desirable sales of goods incorporating the innovations. For example, economic thinking suggests that the copyright doctrine of 'fair use,' permitting for instance limited excerpting from a book for inclusion in teaching materials, might be socially desirable. This excerpting probably does not reduce book sales or the financial motive to author books (indeed, limited excerpting might increase sales of a book because it serves as a form of advertising), whereas the excerpting benefits teaching, because it means that teaching materials can be rapidly assembled without added cost. Most rules of intellectual property law are viewed against the background of their influence on incentives to innovate and on the sale and dissemination of goods embodying innovations.

Contract Law

A primary issue addressed in economic analysis of contract law is that of contract formation. The basic rule of contract formation is that a contract is legally recognized when and only when both sides have given explicit assent, such as by signing a document. This rule is said to be desirable for two reasons. First, it obviously enables parties to make a contract. Second, it protects parties from becoming bound against their wishes due to their having engaged in negotiations; this protection against unwanted obligations is beneficial because, without it, the negotiations that lead to the making of contracts would be inhibited.

Another issue surrounding contract formation concerns legal duties to disclose information. Economic analysis emphasizes that the social desirability of disclosure depends on the situation. For example, disclosure of a material defect (such as a leaky basement) in the home that the owner seeks to sell tends to be beneficial; for if the buyer knows about the defect, he can take steps to avert harm (avoid storing valuables in the basement or repair it). But should an oil company that learns, through costly investigative effort, that oil lies under a parcel of land, be required to disclose this information to the seller of the parcel? Perhaps not: the effect of such a disclosure obligation would be to make oil companies pay substantially more for parcels of land that they learn are romising, and thus to discourage expensive investigation of the location of oil deposits. Note from the foregoing that the economic analysis of legal rules about disclosure obligations concerns their effects on outcomes and does not derive from a possible moral call to tell the truth.

The most developed aspect of economic analysis of contract law deals with enforcement of contractual agreements. Enforcement is accomplished mainly by requiring parties who commit breach to pay the victims of breach for harm, to pay them 'damages.' One effect of the requirement to pay damages is that it induces contractual performance, which tends to raise the value of contracts to the parties and to society. A less obvious advantage of damage payments is that they constitute an escape hatch that parties can use when contractual performance becomes difficult, for they can breach and pay damages rather than bear very high costs to perform. This escape hatch element of damage payments also raises the value of contracts, as it makes parties more willing to assume contractual obligations. The escape hatch feature of damages for breach is also socially advantageous – it is not socially desirable for parties to perform when the cost of so doing outstrips the benefit to the recipient of performance. These points and others (notably, concerning risk allocation, and incentives to invest) regarding the virtues of payment of damages for breach have been analyzed intensively in the economic literature on contracts.

The orientation of economic analysis of contractual enforcement, through damage payments for breach, is very different from that of traditional legal analysis. Under the latter, damage payments for breach tend not to be regarded as incentives toward performance or as implicit escape hatches. Damage payments are seen primarily as compensation for harm or as proper desert for the wrong of breaking a promise. It should be added that, under the economic view, breach of a contract should not necessarily be identified with breaking a promise. The contracts that are written are not interpreted as detailed promises that parties truly want to be kept, but rather as incomplete promises that are only rough guides for behavior, and that the parties do not want to govern when performance would be very difficult.

Economic analysis of contracts has also been concerned with specific classes of contracts, including principal and agent contracts, insurance contracts, financial contracts, and donative contracts; the literature on some of these contractual contexts is now highly refined.

Litigation

One aspect of the economic analysis of litigation describes the motive to bring suits in terms of the potential plaintiff's costs of suit, the likelihood of success at trial, and the amount that would be obtained in the event of success.

Another element of the analysis of suit concerns the issue of whether the number of suits is socially excessive (is there a litigation explosion?) or perhaps socially inadequate. In this regard, it is observed that when a person considers suit, he does not factor in, as a cost to himself, the defendant's legal costs or the state's costs. This indicates that plaintiffs' incentives to bring suit may be socially excessive and thus that suit should be curtailed or barred in some domains. Yet a person considering suit will not usually take into account the deterrent value of the

suit – the message that suit will send, which will affect the behavior of others in the future – as well as any additional, wider social benefits. This divergence between the private and the social benefits from suit suggests that in some contexts the number of suits brought might be inadequate, and that public promotion of suit might be desirable.

Given that suit has been brought, the question arises whether the parties will settle their dispute or proceed to trial. The thrust of economic analysis of this question is that settlement is likely when the beliefs of the two sides about the trial outcome are similar, but that trial is likely when the plaintiff is much more optimistic than the defendant. For example, suppose that the beliefs of both sides are identical – each thinks the plaintiff would definitely obtain $100 000 at trial – and that the trial expenses of each would be $10 000. Then the plaintiff should be willing to accept as little as $90 000 (that is, $100 000 minus his litigation costs) in a settlement, and the defendant should be willing to pay as much as $110 000 ($100 000 plus his litigation costs). Hence, there should be room for settlement (any amount in between $90 000 and $110 000). If, however, the plaintiff's estimate of his winnings is much higher, say $200 000, than the $100 000 the defendant expects to pay at trial, the plaintiff would demand at least $190 000, which exceeds the $110 000 the defendant would be willing to pay. Accordingly, trial would be likely.

Economic analysis of litigation has also begun to address topics beyond the general ones of the bringing of suits and of settlement decisions. Among the topics considered are disclosure of information before trial, appeal of trial outcomes, class actions, and alternative dispute resolution.

Law Enforcement and Criminal Law

An additional area of economic analysis concerns public enforcement of law: the use of enforcement agents (such as police, safety inspectors, auditors) to detect violations of law; and the imposition of penalties for violations.

A theme of the literature on law enforcement is that the magnitude of penalties should be inflated from the level that would be appropriate were detection of violations certain. Inflation of penalties is needed to maintain deterrence, in effect to compensate for the possibility that a violator will not be detected. For example, if a polluting firm that causes harm of $10 000 is detected only a third of the time, then the fine that is imposed when the firm is detected should be not $10 000, but this amount multiplied by three, or $30 000. For, if the fine when the firm is detected is $30 000, the firm's probability-discounted, or average, fine is one-third of $30 000, or $10 000, providing it with incentives not to pollute similar to those that would exist if it paid a certain fine equal to the $10 000 harm.

Another point of emphasis in enforcement literature is that, because law enforcement is expensive, it will often be desirable for society not to spend so much on enforcement as to detect violations with high probability: it may be best, all things considered, to conserve on enforcement resources even though this means that many violators will escape detection. To combat the problem of inadequate deterrence that might accompany a low level of enforcement, multiplied penalties can be applied, as just discussed. Thus, there is appeal in employing an enforcement strategy that involves significant chances of escaping punishment combined with high levels of penalty. However, a problem with this low probability-high penalty strategy is that high penalties may be infeasible. Monetary penalties cannot exceed the assets of violators, which may be quite modest. Also, jail sentences can only be so long, and sanctions that conflict with retributive justice – sanctions that are out of proportion to the gravity of a bad act – might be resisted by the public.

A further issue examined in the economic literature on enforcement is the socially desirable choice between fines and imprisonment as forms of penalty. Here, it is generally said that fines are preferable to prison sentences, because fines do not themselves deplete social resources (but rather transfer command over resources from violators to the state). Whereas, imprisonment does diminish social resources, for prisons are expensive to operate, deprive individuals of their liberty, and prevent individuals from participating in the labor force. Therefore, the economic prescription is that fines be employed as the form of penalty when possible. But when fines cannot be used to deter, because the appropriate fines exceed the assets of violators (the typical robber could not be deterred by the threat of fines, given his level of assets), imprisonment should frequently be employed as the form of penalty. A closely connected point is that when fines cannot be used to deter, imprisonment may be useful as a penalty not only because it may deter, but also because it will incapacitate, that is, prevent individuals from doing further harm while in prison.

The foregoing conclusions and associated ones have been applied to criminal law. It has been suggested that many of the undesirable acts that are punished under criminal law (robbery, murder, rape) have the feature that civil suit and fines would not suffice to achieve adequate prevention of the acts. Therefore, imprisonment is often necessary to deter and to incapacitate those who commit the acts. Further, the magnitude of sanctions under criminal law has been related to the likelihood of detection of the acts, among other elements. Additionally, various doctrines of criminal law have been interpreted as desirable from the economic perspective. For example, that the sanction for murder committed in the heat of passion is less than that for premeditated murder is said to be rational: the ability to deter acts carried out in the heat of passion is relatively low, implying that it would be a mistake for society to incur the costs of the higher level of sanctions that are imposed for planned acts for which deterrence is more effective. Economic analysis of criminal law is concerned generally with the efficacy and the social costs of enforcement and the imposition of sanctions, and does not usually view punishment as a means of achieving retributive justice or other ideas of desert.

Additional Areas of Research

Economic analysis has been brought to bear on a host of other areas of law. These include many business-related areas of law, such as corporate law, tax law, antitrust law, and bankruptcy law, as well as, increasingly, diverse other areas, such as family law, anti-discrimination law, and constitutional law. Moreover, economic analysis has addressed questions surrounding the role of legislative bodies in formulating and enacting legal rules

and the role of courts and regulatory agencies in applying legal rules.

Foundations of, and Criticism about, Economic Analysis of Law

Economic analysis of law is premised on the general assumptions of the discipline of economics. These assumptions and their relationship to economic analysis of law in particular are sketched here. Certain commonly encountered criticisms of economic analysis of law are also mentioned.

Basic Assumptions

With regard to prediction of behavior, the usual assumption made in economics is, as noted at the outset, that parties are forward-looking and rational. This assumption is sometimes criticized as unrealistic. However, the assumption is usually made with the understanding that, although it is best for predicting central tendencies in behavior, various psychological and cognitive biases also influence behavior, and that these sometimes should be taken into explicit account. For example, the propensity to underestimate certain classes of risk, and thus for individuals not to take proper precautions or to insure adequately against them, has been recognized in economic analysis of law.

With regard to the evaluation of outcomes under the economic framework, the well-being or 'utility' of a person is basic. Economists' conception of utility is completely general and reflects not only the material pleasures of life to a person, but also, for example, the influence on his/her happiness of the treatment of others. From the utilities of individuals, a measure of social welfare is constructed, but there is no single, objective measure of social welfare that analysts study. Thus, utilitarianism is just one among a continuum of measures of social welfare that could be examined. The only significant presumption that is ordinarily made is that the measure of social welfare depends exclusively on the utilities of individuals. This assumption is consistent with concerns for equity in the distribution of utility and wealth, and economists have studied the implications of such concerns in depth.

Notions of Fairness and the Law

As has been seen in Sects. 1 and 2, classic notions of fairness, such as corrective and retributive justice, typically are omitted from the evaluation of legal rules under the economic framework, whereas these notions are traditionally viewed as of great significance to the assessment of the law. The essential reason that, under welfare economics, the notions of fairness are not accorded intrinsic importance is the assumption that they do not directly enter into individual's wellbeing. For instance, whether punishment is in proportion to the seriousness of a crime is ordinarily assumed not to affect individuals' utilities *per se;* rather, punishment may affect individuals' wellbeing through its deterrent or incapacitative effects. Because satisfaction of notions of fairness is presumed not to raise individuals' wellbeing in a direct manner, granting these notions independent weight in the evaluation of outcomes would tend to alter social decisions in ways that lower individuals' wellbeing.

Nevertheless, several qualifications to the last paragraph should be made. First, the assumption that notions of fairness do not matter to individuals may not always be apposite: individuals may have tastes for adherence to notions of fairness (individuals might feel happier if punishments fit crimes). To the extent that that is so, satisfaction of a notion of fairness properly enters into individual wellbeing and thus into social welfare, just as satisfaction of a taste for a material good does. (Notice that the importance of notions of fairness as personal tastes, being contingent on what the tastes of individuals happen to be, is different from the intrinsic importance accorded to conceptions of what is fair and right under deontological philosophical views.) Second, notions of fairness tend to have a desirable functional role (punishment only in proportion to the gravity of bad acts tends to discourage bad acts at relatively low social cost). Thus, advancing notions of fairness and inculcating them in the population (perhaps partly through adoption of legal rules that embody them) may serve to promote social welfare.

Income Distributional Equity and the Law

It may have been noted in Sects. 1 and 2 that the income distributional effects of legal rules were not mentioned as relevant to their evaluation under welfare economics, even though, as noted in Sect. 3.1, distributional equity does enter into the assessment of social welfare. The reason that the income distributional effects of legal rules are usually not considered in their evaluation is that economic analysis suggests that the income tax system (combined with income transfer programs) is a better means of achieving distributional objectives than the legal system. The income tax system is overtly redistributive, reaches all individuals, and is relatively cheap to administer. The legal system is not well designed to redistribute: it directly affects only those individuals who are involved in litigation; and even among them, the legal system is difficult to employ to effect redistribution, for a given class of litigants is often comprised of individuals with widely varying incomes (consider the class of victims of automobile accidents). Furthermore, the legal system is a very expensive device for transferring income. Hence, according to economic analysis, the legal system should not be used as a tool to achieve distributional goals, and if legal rules turn out to have undesirable distributional effects, these can be remedied through adjustment of the income tax system.

Economic Explanation of the Law

Finally, a strand of economic analysis should be mentioned claiming that the legal rules that are observed can be explained as those which best advance social welfare. This hypothesis seems attractive at a very gross level of description (for instance, that liability is imposed for causing harm, rather than for doing good, is explainable in the sense that such liability discourages harmful acts); and sometimes the hypothesis is appealing at a fairly detailed level. However, many, if not most, economic analysts hold a nuanced view of the economic rationality of the law, for many legal rules do not have obvious economic rationales, and a number undoubtedly reduce social wellbeing.

Abstract

This article surveys the importance of empirical work in the economic analysis of law. It describes the history of economics as a positive science and then explains how the positivist approach has in recent years led to an increased emphasis on empirical scholarship within the field of law and economics.

Introduction

Since the beginning of the twentieth century, economists have endeavored to conduct economics as a 'positive science.' Under this project, assumptions about reality are combined with the logic of optimization theory to deduce positive predictions about how people will respond to changes in the relevant economic environment. Empirical work testing either the realism of the assumptions or the veracity of the predictions is essential to this undertaking, to ensure that the economic model is a useful abstraction of the examined problem.

As in the consideration of other problems, empirical work is essential to the economic analysis of law. Indeed, because many legal topics are outside the traditional subject matter studied by economists, the traditional assumptions of the neoclassical economic model do not always fit well in the analysis of these problems, and empirical work is especially important to make sure that the logical conclusion of the economic model is relevant to the examined problem. Also, owing to the overlap of the examined subject matter with that studied by other disciplines, the need to examine basic assumptions and the shared statistical methods, empirical work in law and economics can serve as a touchstone for multidisciplinary discourse on law.

Economic Analysis

Economics first developed as a discipline in the seventeenth century, in close association with political science and sociology. During this early period of development, the social sciences enjoyed considerable overlap in examined problems and methodology. Although some works from this time can be identified as being distinctly 'economic,' early social scientists such as Adam Smith (1723–90), Karl Marx (1818–83), and John Stuart Mill (1806–73) hypothesized about economic, social, and political institutions with equal skill and aplomb. This close association between the social sciences continued into the beginning of the twentieth century with the work of institutional economists such as John R. Commons, and economically oriented sociologists such as Emile Durkheim and Max Weber. Indeed, Weber, one of the most distinguished sociologists of his time, held several academic positions as an economist.

However, early in the twentieth century, economics began to separate from the other social sciences in two important ways. First, economics began to diverge in terms of its examined subject matter. Economists began to focus more on studying the machinations of the market, leaving subjects such as social relationships and political economy to the other disciplines. Since the work of Gary Becker (1968, 1976), however, this trend has been reversed, so that now economists study a wide variety of social and political phenomena, including the law. Second, economics began to diverge in terms of its adopted methodology. Although all of the social sciences adopted modern statistical methods for analyzing quantitative data, economists also undertook to develop a 'positive science' of economics under the neoclassical model.

Positive Economics

Since early in the twentieth century, most economists have endeavored to develop economics as a positive science analogous to the physical sciences. The ultimate goal of a 'positive science' is to produce theories that describe observed phenomena accurately, rather than offer a normative evaluation of the desirability of the phenomena. Such theories are devised by making assumptions about the world that abstract the essential features of the examined problem, and then using logic to deduce predictions about the as yet unobserved events. The validity of the theory is then confirmed through empirical work, which examines the predicted events and tests the statistical significance of results consistent with the theoretical model. This deductive process, working from theory to data, can be distinguished from the inductive process used by many other social scientists who tend to analyze the data before inductively deriving their theories. Accordingly, for the majority of the twentieth century, most economists aspired to conduct economics as a positive science that deduces empirical predictions from theory and then tests those predictions against data.

The Neoclassical Model

In the development of economics as a positive science, the dominant paradigm has been the 'neoclassical model.' The neoclassical model consists of a set of assumptions that economists make in analyzing problems. This set of assumptions achieved paradigmatic dominance in economics because they proved useful in analyzing market behavior, and because they were mathematically tractable. Under the neoclassical model, economists generally assume that the appropriate unit for

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86049-3

analysis is the individual consumer or firm, individuals and firms rationally choose among available alternatives to select the option that maximizes utility or profits, people's preferences are exogenous to the model, and transaction and information costs are zero. The economists' notion of 'rationality' assumes that people have preferences with respect to all possible states of the world that these preferences are reflexive and transitive, and that the people will select the option they most prefer. The assumption of free information is usually referred to as the assumption of 'perfect information.' It has deceptively broad-ranging implications in that it implies that each person knows the quality of each good and the price of all alternatives, and indeed has the knowledge necessary to enter the market and produce the good if the market for the good enjoys supercompetitive profits. The assumption of zero transaction costs also has potentially far-reaching implications since, as Ronald Coase (1960) has pointed out, in a world of zero transaction costs, everything happens at once. To be sure, the above characterization of the neoclassical model is a crude abstraction from reality. Many of the primary advances in the field of economics over the past century respond to such concerns by refining the neoclassical model to account for monopoly power, asymmetric information, nonrational behavior, principle agent conflicts, and transaction costs. These refinements allow a researcher to model an economic problem with more realism. Nonetheless, the neoclassical model remains a basic starting point for economic theory.

The conduct of economics as a positive science using the neoclassical model tends to separate the work of economists from that of other disciplines. The adoption of the perspective of the individual as the unit of analysis, and the assumption that preferences are exogenous, preclude consideration of the effect of social norms and the process of socialization that are so important to many sociological analyses. The construction of the concept of individual utility based merely on an ordinal preference ranking was undertaken with the purpose of avoiding some of the stickier problems in psychology, thus making the concept 'psychology-free.' Although the assumption of 'rational choice' has become popular in explaining results or building models in many disciplines, including sociology and political science, the economists' well-defined concept of rationality is generally narrower than that used in other disciplines. Moreover, since the other social sciences rely on inductive logic, working from data to theory, they generally make fewer assumptions about what constitutes rational choice. Accordingly, some sociologists have argued that they study rather than assume human rationality.

The Importance of Empirical Work

The assumptions of the neoclassical model are clearly unrealistic, and this fact raises the importance of empirical work in economics. Every analysis of a problem is necessarily an abstraction from reality, ignoring some of the complexities of the real word to focus on others. The art of modeling is to know which simplifying assumptions one can make and still capture the essence of the problem. Of course, an important test of how well a theory captures the essence of a problem is how well it fits the available data. Milton Friedman (1953) has argued that the realism of a model's underlying assumptions is of little importance as long as the model yields good predictive results. Indeed, Friedman has gone so far as to argue that, paradoxically, the most important hypotheses have the most unrealistic assumptions, because a hypothesis is important if it abstracts the crucial elements of a phenomenon in such a way as to explain much of the phenomenon by assuming little. Other economists have argued that there are purposes to modeling beyond mere prediction, such as explaining the phenomenon or providing a catalog of knowledge for future work. As a result, they have argued that there are reasons for considering the realism of economic assumptions that go beyond the simple predictive value of the model.

The Economic Analysis of Law

Beginning with the pioneering work of Gary Becker (1968, 1976), economists have sought to broaden the scope of their inquiry to all aspects of society. This movement has brought economics into a variety of subject matters studied by other disciplines, including the family, education, discrimination, politics, and – of particular relevance to this article – law.

Interest in applying economic analysis to law, however, has not been limited to economists. Indeed traditional legal scholars, and even judges, have shown interest in using economics to help guide legal analysis and law reform efforts. Economic models can help untangle the incentives and predict the efficiency consequences associated with different legal rules. Viewed in this way, economic analysis provides a normative criterion – efficiency – for legal scholars and judges. Despite the fact that law and economic theory has, since the 1960s, had a large impact on legal scholarship, empirical testing of such theory had been relatively limited until recently. In the past decade, however, there has been a large increase in empirical scholarship within law and economics.

Foundational Research in Law and Economics

The law and economics movement had its origin in the work of Gary Becker, Ronald Coase, and Guido Calabresi. Becker (1968) used simple principles of labor economics to analyze the criminal's decision of whether to engage in crime, and derived implications for optimal penalties and optimal enforcement of the law. Coase's (1960) work established the proposition known as the 'Coase Theorem,' showing that, in a world of zero transaction costs, the distribution of resources is invariant to the rule of law. However, Coase later made clear that he considers his work concerning how to minimize the effects of transaction costs in assigning the rule of law under the more realistic assumption of positive transaction costs to be more important. The 'Coase Theorem with positive transaction costs' posits that the efficient distribution of resources will not necessarily occur under any legal rule and that society should minimize the impact of transaction costs by assigning entitlements away from the party that can most efficiently remedy any externality. Calabresi (1970) wrote a classical study analyzing the costs of accidents and suggesting ways in which tort law might be formulated to minimize those costs.

After these initial contributions, an extensive body of work, primarily by legal scholars, has applied the principle of wealth maximization to various legal problems, explaining either how the law can be understood as promoting wealth maximization (Posner, 1998; Rubin, 1977), or how it might be amended to better achieve that objective. The former approach – finding the underlying efficiency within the common law – is sometimes referred to as the positive or Chicago school of law and economics; while the later approach – highlighting market failures and suggesting legal reform to correct such failures – is sometimes referred to as the normative or Yale school of law and economics (Parisi, 2004). These labels, however, can be confusing since some arguments within the so-called positive school are effectively normative justification of the status quo, sometimes critiqued as 'just-so stories' (Schroeder, 2000; Hovenkamp, 1990). In this article, we use the label 'positive' as it is typically used by economists.

This body of research by legal scholars has primarily focused on the common law. Notable examples highlight the tradeoff between negligence and strict liability in tort law (Shavell, 1980); provide a theory for efficient breach of contract (Birmingham, 1969); and analyze the distinction between property and liability rules (Calabresi and Melamed, 1972). Cooter and Ulen (2012) provide a textbook overview of foundational research in law and economics, and several additional contributions are summarized and excerpted by Katz (1998).

Empirical Work in Law and Economics

Until recently, empirical work in the economic analysis of law has been rather slow to follow these theoretical advances. Nonetheless, some notable early studies have been done directly on issues important to the economic analysis of law. One of the earliest significant empirical works in law and economics was Isaac Ehrlich's (1975) work showing a deterrent effect from capital punishment. Ehrlich's work prompted enormous academic and public debate on the subject, and his results were later disputed by other scholars. A number of scholars have done empirical work in an attempt to verify or disprove the fundamental implication of Coase's work that, when transaction costs are negligible, the distribution of resources is invariant with respect to the rule of law. Among these works, perhaps the most notable for the purposes of this article is Robert Ellickson's (1986) on the distribution of cattle in Shasta County, California, under alternative rules of free range and nonfree range. Ellickson found that Coase was correct that changes in the rule of law did not affect the distribution of cattle; however, Ellickson attributed this finding more to the sociological reason that neighbors had informal means of dealing with animal trespasses that were not influenced by changes in the law, than Coase's reasoning that neighbors would just bargain around inefficient assignments of entitlements. Kip Viscusi (1983, 1992) has also made important empirical contributions in the economic analysis of legal issues through his analysis of the valuation of life and limb and the relative magnitude of various risks. Viscusi's work is important in evaluating the efficiency of tort law, workers' compensation laws, and government regulation of various workplace and environmental risks. Finally, John Donohue (1998) has done important empirical work documenting employment discrimination and the positive impact of law in ameliorating this problem.

The above were certainly not the only notable empirical studies during this time. Nonetheless, the relative paucity of empirical work during this period is worth noting. Writing in 1989, Posner (1989: 58–59) laments that "it continues to be the case that a disproportionate share of economic studies of law lack a substantial empirical component." This problem continued a decade later. Using data from 1972 to 2002, Landes (2003) finds that the frequency of empirical work in peer-reviewed law and economics journals is significantly lower than in economics journals generally. By overlooking the vast body of law and economics research published in law reviews, which are significantly less likely to publish empirical work, Landes (2003) likely understates the gap in empirical research. At least during the twentieth century, law and economics research was subject to less empirical scrutiny than most work in the broader discipline of economics.

There may be several overlapping reasons for the relatively low level of empirical output during the above time period, which possibly include a lack of training in empirical methods among legal academics, a lack of resources dedicated to such work, a lack of preexisting databases during this period for empirical analysis in law, a lack of prestige and incentives attached to such work (Landes, 2003), and perhaps even some fear of exposure to falsification through replication on the part of other scholars. But whatever the exact reason the situation has changed markedly in the 10 years since Landes' (2003) study.

In the past decade, law and economics scholars have produced empirical work at a much higher rate than previously. This is part of a broader move toward empirical scholarship within legal academia generally (George, 2006); but the effect is particularly pronounced within the law and economics community. Following Landes' methodology, we calculate the percentage of papers published from 2011 through the first issue of 2013 in *The Journal of Legal Studies* (JLS) – a leading law and economics publication – which contain empirical content. Out of a total of 37 JLS articles during this recent period, we found that 24 (or 65%) contained a substantial empirical component. By contrast from 1972 to 2002, Landes (2003) only found that 38% of JLS articles contained empirical content. This difference in the rate of empirical scholarship – 38% vs 65% – between the two periods is statistically significant at the 1% level (difference of means t-test), and suggests that there has been a meaningful change in the type of scholarly output produced by the law and economics community. We do not believe this result is limited to JLS, but rather reflects a broader trend in the law and economics community.

Recent empirical work in law and economics takes a number of different approaches. Some articles use data to test predictions from theory, while other projects – such as the following example investigating the cost of medical malpractice – examine policy implications stemming from law reform. Using a comprehensive database of claim outcomes from medical malpractice suits brought in Texas from 1988 to the present, Black et al. (2005) find no evidence of a malpractice insurance crisis; damage awards did not increase from the late 1980s to the present. Furthermore, damage caps – introduced

in Texas in 2003 – appear to have little impact on the overall cost of health care (Paik et al., 2012). These studies have important policy implications for tort reform.

Other scholars investigate whether patent protection stimulates innovation and restricts output as predicted by economic theory. For example, Moser (2012) uses a large data set of British and American inventions presented at world's fairs between 1851 and 1915, and finds the majority of such inventions were not protected by patent. In a separate study, Lakdawalla and Philipson (2012) present data from the pharmaceutical industry showing that output often fails to rise after patent expiration, and suggesting that this result is due to reduced incentives for marketing nonpatented drugs. Both Moser (2012) and Lakdawalla and Philipson (2012) find results contrary to basic predictions from economic theory, and highlight a need for a more refined economic theory of IP protection.

Most empirical work in law and economics is quantitative in nature, and typically involves large-n databases. While working with such data has a number of benefits related to replication and hypothesis testing, it may cause law and economics scholars to overlook topics where quantitative data are unavailable. In contrast to this trend, some empirical work in law and economics does involve qualitative research. Baker and Griffith (2006, 2007), for example, investigate the market for directors' and officers' (D&O) liability insurance policies by conducting semistructured interviews with professionals in the D&O insurance industry. The interviews provide an excellent insight – impossible to glean from quantitative data – into how insurance underwrites price and monitor the risk of corporate governance failure (Baker and Griffith, 2006, 2007). We believe law and economics empirical work would benefit if more projects took advantage of qualitative evidence, possibly alongside quantitative data, to help ensure that the theory is grounded in reality. This quibble aside, the recent increase in empirical research in law and economics is noteworthy.

We consider a number of developments that can help explain why empirical work has become more prevalent within the law and economics community over the past 10 years. First, over the past decade there has been a large increase in joint degree law professors who in addition to a JD have a Ph.D in economics or a related field (Hersch and Viscusi, 2012). Scholars with an economics Ph.D are trained in modern statistical methods and bring with them professional norms of the economics community, including a general acceptance of a positivist approach to research. Furthermore, the increasing presence of Ph.D scholars in law schools has brought greater acceptance within the legal academy of publishing in disciplinary and interdisciplinary journals as opposed to law reviews, raising the reward and lowering the risk of doing empirical work.

Second, under the deductive method favored by positive economics one first needs theory before empirical testing is even possible. Once there are multiple competing models analyzing a given subject, however, there arises an increased need for empirical testing to determine which model more accurately predicts behavior. For example, consider Waldfogel (1998), who uses data on the selection of cases for trial to test two prominent and competing hypotheses – Priest and Klein (1984) vs Bebchuk (1984) – for the choice between settlement and trial. Waldfogel's empirical research was only possible after the underlying theoretical work had been developed. Thus, even within the positivist framework it makes sense that early scholarship in a new field, such as law and economics, would be primarily theoretical, and would then be followed by more empirical testing as the field matures, and as novel theoretical contributions are harder to make. The relative need for theoretical as opposed to empirical research has changed as law and economics has matured.

Third, changes or discontinuities in the law can be particularly useful for purposes of statistical identification. Identification is the strategy by which an empirical study isolates causation as opposed to endogenously driven correlation. In practice, valid identification is a difficult hurdle to clear; however, as statistical methods have substantially improved in recent years the economics community increasingly requires valid identification for publication in top journals. Interestingly, changes in the law or discontinuities in legal treatment are some of the most widely used identification strategies by economic researchers. The use of law for identification purposes has brought several econometricians to the law and economics field. One notable example of such work is Greenstone et al. (2006), which uses a 1964 change in US securities regulation to isolate the effect of mandatory disclosure. The new law extended mandatory Securities Exchange Commission (SEC) disclosure to some, but not all, over-the-counter (OTC) companies. This creates a natural experiment since there is both a control group (the OTC companies unaffected by the new law), and a treatment group (the OTC companies required to comply with SEC disclosure starting in 1964). The study found that treatment group companies experienced positive abnormal returns around the passage of the new law, suggesting that investors value mandatory disclosure (Greenstone et al., 2006). Studies of this sort – which use a change or discontinuity in the law for purposes of statistical identification – are part of a growing trend, increasing both the quantity and quality of empirical research in law and economics.

A final consideration leading to more empirical work in law and economics is the emergence of specialized journals and numerous conferences devoted to empirical legal studies (ELS). The *Journal of Empirical Legal Studies* was first published in 2004 and the Conference on Empirical Legal Studies was first held in 2006. Both the conference and the journal have already had a large impact on legal scholarship, and have been followed by a number of law review symposiums devoted to ELS (Eisenberg, 2011). To be sure, the ELS movement represents a broad trend in legal academia and is not exclusively linked to law and economics. Nonetheless, there is a large overlap between ELS and the law and economics movement, creating additional publication and presentation outlets for empirical research in law and economics.

Empirical Work in Law and Economics as a Touchstone for a Multidisciplinary Discourse on Law

It has become increasingly apparent that empirical work in law and economics can serve as a touchstone for interdisciplinary discourse on law. This is true for several reasons. First,

economics shares the same accepted statistical methods for analyzing data with other social science disciplines, facilitating dialogue between empirical researchers studying the law regardless of the researchers' background. Second, grounding in empirical research encourages law and economics scholars to relax some of the assumptions of the neoclassical model. The traditional economic model of individual rational choice does not always capture the essence of legal problems in the way that it did in the study of atomistic markets.

By relaxing some of the assumptions of the neoclassical model, economists have found that their work becomes less distinct from that of theoretical work in other disciplines. This is true not only for the reason that such economic work is inductive rather than deductive in nature, working from the data to theory, but also because relaxation of some of the assumptions of the neoclassical model allows for the consideration of work from other disciplines. In particular, some law and economics scholars have found connections between their work and the work of sociologists who study law, while other law and economics scholars have made use of empirical work out of the behavioral sciences.

Sociological Influences in the Economic Analysis of Law

Some law and economics scholars have drawn on the work of sociologists. Interest among law and economics scholars in the influence of social norms and the role of law in the socialization process is one example of this trend. In order to examine these phenomena, the economist usually has to relax one or more of the traditional assumptions of the neoclassical model. For example, to examine the influence of social norms on people's behavior, the economist might adopt a perspective of analysis that takes into account group or community interests, rather than just individual interests. Similarly, in examining the role of law in the socialization process, some economists have found it useful to relax the assumption that people's preferences are exogenously determined. With the relaxation of these assumptions, it is also necessary generally to adopt an objective function other than individual utility, wealth, or profit for maximization in the economic model – for example, net social benefits or social welfare.

Although some very interesting work in the study of norms from the economic perspective has been done by McAdams (1997), Cooter (1995), and Posner (1996), perhaps the seminal work on the subject was the work previously alluded to by Robert Ellickson (1986). To test the Coase theorem, Ellickson surveyed land owners in Shasta County, California, as to the number of animal trespass cases they had experienced under different legal regimes, and how those incidents were resolved. Ellickson found that the allocation of resources was indeed invariant to the legal rule, as predicted by Coase. However, Ellickson (1986) found that this result, obtained not because transaction costs were low and the parties had bargained around the law to reach an efficient allocation of resources, but instead because resort to the law was costly, and as an alternative the affected parties were committed to a norm of cooperation with their neighbors, regardless of the rule of law. As a result, Ellickson concluded that law and economics would benefit by considering previous work on such questions in sociology, and the law and society movement. Taking his own suggestion to heart, Ellickson (1998) has used empirical work from other disciplines on norms of 'fairness' and 'civic responsibility' to analyze a variety of legal problems including rent control, the doctrine of unconscionability, the implied covenant of good faith and fair dealing, the duty to rescue, political and judicial processes, and the First Amendment.

Another area in which the economic analysis of law has shown connections to work in sociology is the analysis of the role of law in the process of socialization. In this area, one of the present authors has written an economic analysis of the criminal law as a preference-shaping policy (Dau-Schmidt, 1990). If one relaxes the neoclassical assumption that preferences are exogenous to the model, and instead assumes that criminal law is intended to discourage preferences for criminal behavior, as well as to raise the costs of engaging in such behavior, then one can explain many of the fundamental doctrines of criminal law. Further work on how the law shapes preferences or helps establish new norms – sometime referred to as the 'expressive function of law' – has been done by Cooter (1998) and Sunstein (1996); and empirical testing of the expressive function of law is found in Feldman (2009) (suggesting based on field experiments that the expressive impact of trade secret laws operates primarily through their impact on morality), Funk (2007) (laws removing the obligation to vote led to significantly lower levels of voter turnout in Switzerland, even though the former voting requirement was only symbolic and never enforced by fine), and Wittlin (2011) (finding that seat belt laws increase seat belt usage independent of enforcement). This work lends itself naturally to integration with work from sociology, because it raises questions concerning how law impacts socialization and how law shapes both norms and individual preferences.

Behavioral Law and Economics

Other economists have drawn on the empirical work of behavioral psychologists in their analysis of law. In 'laboratory' experiments, behavioral psychologists such as Amos Tversky and Daniel Kahneman (Tversky and Kahneman, 1982) have established that the human decision-making process typically varies in predictable ways from the simple model of rational choice assumed in the neoclassical economic model. In particular, they have established that people commonly exhibit 'bounded rationality' in that they can only process a finite amount of information and thus must rely on rules of thumb to help them make decisions, 'bounded willpower' in that they sometimes do things that are clearly not in their long-term interests, and 'bounded self-interest' in that they care about other people and whether the treatment in their relationship is reciprocally 'fair.' Tversky and Kahneman have also established that people evaluate outcomes based on the change they represent from an initial 'reference point,' weighting potential losses from the reference point more heavily than potential gains. This finding is referred to as 'prospect theory' in the literature, and it can be exploited to manipulate people's decision-making process by suggesting the initial reference point to 'frame' possible choices as gains or losses.

As with the influence of sociology on the economic analysis of the law, there has been a boom in the number of scholars who seek to use 'behavioral economics' in their analyses of the

law. Early proponents of such work include Thomas Ulen (1989) and Robert Ellickson (1989), but they have since been joined by others including Russell Korobkin (see Korobkin and Ulen, 2000), and Christine Jolls et al. (1998). These scholars argue that amendment of the assumptions of the neoclassical model concerning individual rational choice according to the empirical findings of behavioral economics is necessary to improve the predictive power of the economic model. Their critique is fundamental, in that it goes back to basic assumptions about the purposes of law, and how people will react to and enforce the law. For example, Jolls et al. (1998) have argued that the Coase theorem is often empirically false, because empirical work in behavioral economics suggests that people sometimes develop attachments to objects they possess, and this 'endowment effect' may mean that people must sometimes be paid more to part with an entitlement than they would pay to possess the entitlement. Accordingly, people will not bargain around the assignment of entitlements in the way described by Coase. Similarly, Korobkin has argued that information heuristics will affect the efficacy of tort damages in providing efficient incentives to take care. Because work in behavioral economics shows that people are often overly optimistic in that they undervalue the chances of something bad happening, and overvalue the chances of something good happening, this suggests that, even if tort damages are set at efficient levels, people will not account adequately for the chance of accident and so will not take efficient care.

An interesting behavioral update to Becker's (1968) classic study of deterrence comes from a recent empirical study by Lee and McCrary (2005). Becker (1968) assumes that the same level of deterrence can be achieved either by increasing the likelihood of punishment or by increasing the length of sentence. Lee and McCrary (2005) take advantage of the fact that young offenders are treated as adults – and are thus subject to substantially longer periods of incarceration – after their eighteenth birthday. Thus, Becker's theory would predict a large deterrent effect in comparing 18-year-olds to 17-year-olds. Instead, Lee and McCrary find that the severity of punishment has very little impact on offending rates, whereas increasing the likelihood and immediacy of detection can have a large deterrent effect. Potential offenders appear to be extremely myopic or impatient, and do not behave consistently with standard rational actor assumptions. From a positivist perspective, this suggests that Becker's theory of deterrence, while interesting, is not a predictively useful abstraction of reality. Future theoretical work is needed to better account for the behavioral pattern found in Lee and McCrary's (2005) work.

Conclusion

This article surveys empirical research in the economic analysis of law. We describe the history of economics as a positive science and then explain how the positivist approach has in recent years led to an increased emphasis on empirical law and economics scholarship. We discuss trends regarding empirical methodologies used in law and economics, and also explain how empirical work in law and economics can serve as a touchstone for a multidisciplinary discourse on law.

Law and Emotion

Susan A Bandes, DePaul University College of Law, Chicago, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The field of law and emotion draws from a range of disciplines in the sciences, social sciences, and humanities to shed light on the emotions that pervade the legal system. It utilizes insights from these disciplines to identify and assess the implicit and explicit assumptions about emotion that animate legal reasoning, legal norms, legal doctrine, the behavior of legal actors, and the structure of legal institutions.

Introduction

The field of law and emotion draws from a range of disciplines in the sciences, social sciences, and humanities to shed light on the emotions that pervade the legal system. It utilizes insights from these disciplines to identify and assess the implicit and explicit assumptions about emotion that animate legal reasoning, legal doctrine, and the behavior of legal actors. In light of law's focus on influencing social norms and on structuring effective and just institutions, one development that holds enormous promise is the growing interdisciplinary interest in collective decision-making and in the emotional dynamics of groups. Work in the affective sciences (an emerging interdisciplinary field composed of psychologists, neuroscientists, anthropologists, and other researchers concerned with the role of emotion in human behavior and decision-making) on how emotion and cognition interact is another rich vein for legal scholars interested in the assessment of responsibility and blame, the role of morality in law, and a host of other areas. By reevaluating legal doctrine and policy in light of relevant knowledge from psychology, neuroscience, sociology and other fields, law and emotion scholarship aims to contribute to a more informed and effective framework for refining legal doctrine and reforming legal institutions.

Most fundamentally, law and emotion scholarship challenges standard legal accounts of rational deliberation and legal reasoning. As a descriptive matter, it challenges the deeply ingrained belief that emotion is a hindrance to – or even the antithesis of – rationality. It emphasizes that this belief is increasingly untenable in light of the emerging consensus in the sciences and social sciences that emotion is an inextricable part of the cognitive process. On the normative level, it explores the appropriate role of emotion in the identification and implementation of legal norms and in the deliberative process for juries, judges, and other legal actors.

Second, at the level of specific doctrine, law rests on myriad assumptions, both explicit and implicit, about how emotion influences behavior and about how to channel emotion to influence decision-making in desirable ways. Law and emotion scholarship identifies and scrutinizes these assumptions in light of evolving knowledge about the role of emotion in decision-making across a range of disciplines.

Finally, the field increasingly focuses on emotion not only as an internal and individual phenomenon but also as an essential component of social and institutional dynamics. It thus sheds light on collective decision-making, on the conditions that lead to legal change, and on the dynamics of institutional behavior and institutional reform.

Emergence of the Field

The emergence of modern law and emotions scholarship was fueled by several interrelated trends. Beginning in the 1980s and early 1990s, the topic of emotion began attracting renewed scholarly attention in fields like philosophy (Nussbaum, 1990), psychology (Clore et al., 1994), and sociology (Thoits, 1989). At the same time, cognitive scientists progressed in understanding emotion's role in judgment by studying patients with brain abnormalities or injuries that impair emotional functions (e.g., Damasio, 1994, 1999). More recently, the field of cognitive neuroscience began to employ powerful neuroimaging technology such as functional magnetic resonance imaging and positron emission tomography scans to investigate these dynamics (see, generally, Sinnott-Armstrong, 2008; Jones et al., 2009). The study of the role of emotion in cognitive processes has in recent years become a focal point for a number of disciplines, generating a complex, provisional and rapidly evolving body of knowledge. Although many disciplines hold pieces to the puzzle of emotion's role, there is 'no umbrella discipline to bridge the findings' of these disparate fields (Panksepp, 1998: p. 5).

Concurrent with the explosion of interest in emotion in the sciences and social sciences, legal scholarship grew more open to relevant insights from other disciplines. In addition, epistemological challenges to notions of judicial objectivity first raised by the legal realists were renewed and extended by critical race theorists and other scholars (Abrams and Keren, 2010: pp. 2005–2006). Feminist jurisprudence, in particular, was an important force behind emergent law and emotions scholarship, arguing that law tended to privilege a version of reason that exiled important qualities like empathy and compassion; qualities that were regarded as soft and feminine and therefore lacking in rigor (Minow and Spelman, 1988). The necessary next steps, as Bandes (1996, 2000) argued, were to move beyond the rehabilitation of certain emotions, clarify that no particular emotional stance is likely to be uniformly desirable or undesirable, and turn to more specific consideration of the value of emotions, whether positive or negative, in defined

contexts. Recently the scope of law and emotions scholarship has expanded considerably. It now covers the range of positive and negative emotions, incorporates findings from a wide range of disciplines, and explores multiple doctrinal areas as disparate as securities regulation, risk regulation, personal injury law (Madeira, 2006), foreclosure law (White, 2010), family law, contract law, and trademark law, to name a few.

Definitional Issues: What Is Emotion? What Are Emotions?

One continual challenge of this emerging field is defining its central term: emotion. Terms for particular emotions, such as remorse, disgust, or fear likewise elude fixed definitions, both across and within disciplines. As Jerome Kagan points out, for example, a neuroscientist seeking to measure fear responses in lab rats, an anthropologist studying fear responses to the approach of strangers, and a child psychologist studying separation anxiety all use the term 'fear,' but describe different agents, targets, contexts, methodologies, and research goals, and these need to be specified to facilitate interdisciplinary interchange (Kagan, 1998: pp. 14–38). A common error for jurists and legal scholars is to deploy such terms as if they have stable meanings not only within individual disciplines but when transported to the legal realm (Bandes, 2009b: pp. 8–13). Ideally, those who deploy the category 'emotion' or terms describing emotions in the legal realm will clarify their working definitions, the context in which the terms are being used (Kagan, 2007: p. 41), and what legal consequences flow from the use of the terms.

In the conventional legal view, emotions are unpredictable, untamable bursts of feeling that are too ephemeral to study and too instinctual to channel or educate. However, current research across several disciplines paints a very different picture. Although any definition must be provisional, emotions can be better described as a set of evaluative and motivational processes, distributed throughout the brain, that assist us in appraising and reacting to stimuli, and that are formed, interpreted, and communicated in social and cultural context. They influence the way we screen, categorize, and interpret information; influence our evaluations of the intentions or credibility of others; and help us decide what is important or valuable. They drive us to care about the outcome of our decision-making and motivate us to take action, or refrain from taking action, on the situations we evaluate. In short, they are pervasive influences on human behavior, and therefore essential for a full understanding of legal behavior and institutions.

Identifying and Investigating Law's Affective Dimensions

Scholars have investigated the role of emotion in a wide range of legal contexts. Maroney's (2006) law and emotion taxonomy provides a valuable organizing framework for scholars across the range of disciplines. Recent comprehensive overviews of the field by Abrams and Keren (2010) and Bandes and Blumenthal (2012) convey the range of the scholarship. Three main approaches to the study of law and emotion are discussed below.

The Role of Emotion in Doctrine

Legal doctrine sometimes rests on explicit assumptions about emotion. For example, in the criminal law, the practice of imposing shaming punishments is premised on the assumption that such punishments will encourage offenders to change their ways. In the law of evidence, the excited utterance exception to the hearsay requirement is premised on the assumption that a statement delivered in an excited state brought on by a startling event is more likely to be reliable. More often, law's assumptions about emotion are implicit. This makes them more difficult to identify, but no less likely to lead to the imposition of legal consequences. For example, Calhoun (2000) argues that objections to same-sex marriage rest upon implicit assumptions about who is capable of romantic love. Lynch and Haney (2011) have found that in capital sentencing proceedings, the jury's perception of whether the defendant displayed appropriate remorse is one of the main factors – and perhaps the most important factor – in determining whether the death penalty is imposed. More subtly, assumptions about what counts as emotion may influence legal doctrine in ways that go undetected. For example, appeals for mercy may be coded as emotional and off-limits, whereas appeals for vengeance or retribution may be coded as garden-variety legal arguments (Bandes, 2009a: pp. 497–498).

Much of the importance of the scholarship on law and emotion lies in exploring the ways in which the categories of reason and emotion are deployed and in "challenging the notion of a neutral, emotionless baseline" in legal theory and practice (Bandes, 1996: p. 370). Once the assumptions about emotional dynamics that pervade the law are identified, their accuracy can be evaluated in light of scientific and social-scientific knowledge. Whether a gap between law and science ought to lead to revising doctrine is a legal question, but one that ought to be made in light of the relevant available information about how emotions work.

The Role of Emotion for Various Legal Actors

There has long been available a robust empirical literature on jury decision-making (see e.g., Diamond et al., 2010), which has recently begun looking specifically at juror emotion (see e.g., Sundby, 2003) and at how the collective dynamics of the jury room differ from the emotions of individual jurors (see Lynch and Haney, 2011). It has more recently been joined by a literature on the role of emotion in negotiation (e.g., Ryan, 2005). Nevertheless, the question of what role emotion plays or ought to play in the reasoning process of particular legal actors or legal entities – for example jurors as a collective entity, legislators (see Sanger, 2012), or judges – is ripe for investigation. The emotions of judges have received scant attention until recently, when the emotional dynamics of judicial decision-making attracted substantial interest, prompted in part by controversy over the role of empathy in judging (West, 2012). Scholarship has focused both on how judges deliberate (see, e.g., Posner, 2008) and on how the emotional dynamics of judicial deliberation affect judges (see, e.g., Maroney, 2011b; discussing how judges do and should regulate their emotions).

The Role of Emotion in the Reasoning Process

Although it is widely agreed that emotion plays a role in the cognitive process, the question of precisely what that role entails is the subject of lively debate and substantial research across disciplines. It is clear that emotion influences not only 'the *content* of cognition' but also '*how* people think' (Forgas, 2001: p. xiv). They affect what stimuli draw attention, what meaning is attached to observations, and what details remain in memory (Phelps, 2012: p. 19). Feigenson identifies several paths through which emotion may influence judgment, including: (1) by affecting people's strategies for processing information; (2) by biasing the perception, recall or evaluation of facts in a particular direction; (3) as a source of informational cues to proper attribution of blame; and (4) through anticipation of future emotions that might follow from a judgment (Feigenson, 2010: pp. 46–47).

Emotion's Informational Role

Emotions may affect judgment directly, by providing informational cues about the judgment target. This path to emotion's influence on judgment is described in the literature as 'affect-as-information' (Clore et al., 1994). (The terms 'affect' and 'emotion' are often used interchangeably.) For example, a witness's testimony may elicit unease or mistrust; a crime may elicit anger toward the defendant and sympathy toward the victim; a judicial decision may elicit outrage; a victim's testimony may elicit sympathy, a public event may evoke fear or sympathy that triggers a push for legislation. At bottom, whether the information provided by these emotional reactions is relevant or useful is a legal question, dependent in part on the legal context and the goals of the proceeding (for example anger toward a defendant might be relevant to sentencing but not to guilt). More broadly, it is a jurisprudential question about what factors and values ought to influence legal judgment. Studies lend increasing support to the conclusion that emotion is integrally involved in moral judgment. The question of whether 'moral' emotions and capacities, such as moral indignation, outrage, disgust, compassion, and empathy, ought to influence legal norms and judgments (Kahan, 2000; Nussbaum, 2000) is intertwined with longstanding debates about the role of moral reasoning in legal judgment.

Emotion's effects on information processing

Studies have shown in several contexts that heightened emotion increases the likelihood of a criminal conviction, at least in mock juries. There is evidence that 'gruesome' photographic evidence increases mock jurors' negative emotional state, and usually leads to increased conviction rates. Mock jurors have been found to be unable to disregard emotionally charged evidence when instructed to, and the emotional content of such evidence has been tied to increased guilt and sentence ratings. Victim impact statements have been found to elicit anger at the defendant, and that anger has been linked to increased sentence severity (Nadler and Rose, 2003: pp. 24–26; Salerno and Bottoms, 2009: pp. 284–285). Feigenson and Park (2006) and Maroney (2006) summarize many other studies of emotion's impact on legal judgments. As Feigenson suggests, emotion may influence judgment in these contexts through several paths. For example, the emotions affecting the decision-maker may influence strategies for processing information. Sadness has been linked with careful information processing. Anger, on the other hand, has been found to exert a negative effect on judgment – leading to shallower information processing, greater reliance on heuristics and biases, and greater confidence in the accuracy of one's judgment. Alternatively, a decision-maker's emotions may bias the perception, recall, or evaluation of facts in a particular direction. They may lead the decision-maker to seek out emotion-congruent information, and to ignore or downplay incongruent information. For example, anger at a criminal defendant may lead jurors to focus on evidence that validates their negative reactions and to discount mitigating evidence. Much work remains to be done identifying the specific emotions at play in various contexts and their mediating effects on judgment.

Identifying and Interpreting Emotion

One of the central roles of legal decision-makers is to interpret and evaluate the intentions, beliefs, and motivations of others. The affective sciences and social sciences offer several promising approaches to studying the dynamics of communicating and interpreting emotion.

Nonverbal Expression of Emotion

The study of the communication of emotion through facial expression and body language is a burgeoning field. As noted above, significant legal consequences may turn on how facial expressions or body language are interpreted – for example on whether a defendant looks remorseful (Weisman, 2009). Researchers in this field focus on issues highly germane to law, including whether facial expression of emotion is culture-specific, and whether facial display conveys information about the expresser's social motives and intentions (Niedenthal et al., 2006: p. 116).

Cultural Expectations for the Feeling and Display of Emotion

A second approach to understanding the dynamics of communicating and interpreting emotion is the study of schemas and cultural expectations about how emotion ought to be expressed in various contexts (see, e.g., Hochschild (1983) on feeling rules and display rules). The credibility of a range of legal actors may be influenced by whether they display the emotions expected from those in their role (e.g., whether a rape complainant expressed the emotions the decision-maker expects from a rape victim (Schuster and Propen, 2011)).

Empathy

A third research area focusing on the communication and interpretation of emotion is the social neuroscience of empathy, which sheds light on how individuals understand the minds, desires, and motivations of others (for an excellent compendium, see Decety and Ickes, 2011). This area also has important implications for law.

The role of empathy in law has been much discussed recently, specifically in the judicial context, as mentioned above. The debate, in law as in other disciplines, has been bedeviled by

definitional ambiguities. Neuroscientific studies of empathy are helping to disambiguate the neural underpinnings of various types of empathy, some of which also go by such names as sympathy and compassion (Batson, 2009). These definitional ambiguities are relevant to legal and political debates over the role of empathy in judging. For example, some concerns about judicial use of empathy are based on the notion that empathy entails a sentimental attachment to – or a desire to offer assistance to – one of the parties to a controversy and is thus inconsistent with impartiality. This concern may be well-founded if empathy means an 'impulse to respond with sensitivity and care to the suffering of another' (Batson, 2009: p. 9). However, if empathy consists of understanding the thoughts and feelings of another (Batson, 2009: p. 4), then it is, arguably, an essential capacity for judges (Posner, 2008: p. 117; West, 2012).

Moreover, the dynamics of empathy are relevant to law in much broader contexts. If empathy is the capacity to understand the thoughts and feelings of another, it becomes clear that it is not an occasionally employed sentiment or a sentiment directed solely at those less fortunate, but a tool that is in constant (albeit not always accurate) use in legal decision-making. Thus it is important to investigate how empathy is employed in a variety of legal contexts. For example, studies suggest not only that juries have difficulty empathizing with defendants from other racial and demographic backgrounds (Lynch and Haney, 2011), but also that juries in homicide cases tend to feel more empathetic toward some homicide victims than others and that this selective empathy influences their verdicts (Sundby, 2003). The science and social science of empathy also point the way toward the possibility of addressing empathy deficits or selective empathy; empathy appears to be a capacity that is eminently trainable (Feshbach and Feshbach, 2011).

Implications for Implementation and Reform

As the foregoing discussion illustrates, the relationship between law and emotion is multifaceted. Therefore, the reforms to which insights from law and emotion scholarship point may take many forms. One approach to reform is revision of legal doctrine that rests on erroneous assumptions about emotion. An even broader challenge is to channel and regulate the emotions of legal actors, and to apply the insights of emotion theory to the structure and function of legal institutions. The following section briefly discusses several possible approaches to legal reform. It briefly discusses the revision of doctrine and the management of the emotions of legal actors. It then turns to the question of how legal institutions might be structured in light of insights about the role of emotion in legal and moral decision-making.

Doctrinal Revision

Where legal doctrine relies on erroneous assumptions about emotions or emotional dynamics, is ought to be reconsidered. To take a straightforward example, shaming sanctions are meant to deter and rehabilitate, and if it can be established that they have the opposite effect – that instead they stigmatize and marginalize offenders in a way that interferes with both these goals – then shaming sanctions serve no legitimate penal purpose and should no longer be imposed (Massaro, 2000). Whether a disconnect between legal standards and scientific or social-scientific knowledge requires a change in legal doctrine is ultimately a legal question, but one that should be informed by relevant scientific and social-scientific knowledge.

Managing Emotions

On the individual level, numerous studies show that people are able to regulate or manage the emotions they experience, whether by reconstructing aspects of a situation, shifting attention, reappraising reactions to a situation, or avoiding situations that might elicit a particular emotion (see Maroney, 2011a; reviewing the literature and applying it to the ability of judges to manage their emotions). Much of the primary emotion regulation and management research thus far has focused on the coping strategies and psychological health of individuals. Thus, an important avenue for law and emotion research will be to move this line of research into decision-making generally and legal decision-making in particular.

Educating and Channeling Emotions through Structural Reform

A fertile area for research is the question of whether, and under what circumstances, emotions can be educated. Both unconscious and conscious emotions influence legal decision-making, and either type of emotional influence may be desirable or deleterious, depending on the context. Indeed it increasingly appears that all decision-making has both unconscious, intuitive components and slower, more conscious components. Emotion-based capacities such as empathy, as discussed above, appear to be highly educable. There is some evidence that this educative capacity exists not only for emotions in conscious awareness, but even for intuitive, unconscious emotions, implicit biases, and stereotypes (Blumenthal, 2010: pp. 196–198). To construct legal institutions capable of channeling and educating both conscious and unconscious emotions, it is necessary to understand the complex interplay between the two. This requires examination of dual-process theories generally and in the context of moral decision-making.

Dual-Process Theories

Most current theories of cognition adopt a dual-process approach, involving some combination of quick, intuitive judgments and slower, more deliberative judgments (Kahneman, 2011). Much of the debate centers on how the two processes interact. The least nuanced dual-process models treat the two systems as quite separate, and treat the quick, intuitive process as inferior – a path to be taken only when there is insufficient time to deliberate properly. One pitfall to watch for in the dual-process model literature is slippage between the concepts of intuition and emotion. Scholarship in law, political science, and other disciplines, to some extent abetted by the neuroscientific literature itself, too often equates 'intuitive' with 'emotional' and 'deliberative' with 'reasonable,' replicating the problematic dichotomy between emotion and reason. Not all quick, intuitive judgments are emotional in nature, and emotion influences slow, deliberative judgments in addition to quick intuitive ones. Fortunately, dual-process

models are increasingly sophisticated, recognizing that the processes are highly interconnected and interdependent. Two of the most prominent dual-process theories are discussed below in the context of moral decision-making.

Moral Decision-Making

Greene and colleagues (e.g., Greene et al., 2001) suggest that some moral decisions "engage emotional processing to a greater extent than other(s), and these differences in emotional engagement affect people's judgments" (p. 2106). They argue that emotion automatically and unconsciously influences personal but not impersonal moral decisions. This theory has interesting implications for jury decision-making in general, for more specific issues like the use of videotaped testimony, and for the validity of mock jury studies, among other issues.

In Haidt's (2001) social-intuitionist theory, moral decision-making is intuitive, fast, unconscious, and automatic. According to this approach, stimuli lead to instant, affect laden feelings of moral approval or disapproval and these feelings cause moral judgments (p. 814). Haidt argues that moral intuitions are difficult to override, and that conscious reasoning is often merely a post-hoc way to explain our initial moral intuitions. Nevertheless he identifies several means of overriding or at least revising these strong intuitive responses. These include using conscious verbal reasoning and reframing a situation in a way that triggers a competing intuition. If Haidt is correct that moral judgment comes first, followed by a reasoning process that is designed to explain rather than revise the initial intuition, his model has, at minimum, important descriptive implications for our understanding of how judging and other deliberative processes occur.

Dual-process dynamics can help shed light on how intuitive emotions might be channeled or tempered by the legal system where appropriate. Along these lines, Sunstein (2009) has explored the emotion of moral indignation as a species of intuitive processing that provides valuable information to the legal system but that often needs to be tempered by more reflective reasoning, and has considered how various legal institutions and processes (including homicide trials, administrative and legislative risk regulation, and punitive damage assessments) ought to be structured to ensure that both intuition and deliberation play their appropriate roles. Moreover, Haidt (2001) and others argue that moral judgment flourishes not in isolation but in situations of social interchange, particularly with those who hold different perspectives. The implications of dual-process models for the structure of deliberative institutions like the jury and the judicial system are well worth exploring.

Emotion in Group and Institutional Settings

The conventional focus across disciplines on emotions as private and internal feelings has been enormously limiting, both in general and in the legal context. Just as emotions are shaped by social and institutional context, institutions are constructed in light of assumptions about emotional dynamics. In the legal realm, as elsewhere, these assumptions are ripe for scrutiny in light of a growing body of interdisciplinary knowledge about emotion in collective and institutional settings (Bandes, 2009b: p. 394).

Recently, a number of disciplines have begun to focus on emotion in social context. The sociology of emotion is now a burgeoning field (Turner and Stets, 2005). Psychologists are increasingly interested in emotion and social cognition, in emotion's role in group dynamics (Parkinson et al., 2005), and in the interaction between emotion and culture (Niedenthal et al., 2006), an interest they share with anthropologists (Lutz and White, 1986). Political scientists are exploring the role of emotion in democratic deliberation (Westen, 2007; Krause, 2008). The emerging field of affective neuroscience is examining the neural dynamics of emotional interchange (Panksepp, 1998). Criminologists are looking at the role of emotion in a variety of contexts, including the formation of punitive attitudes, the dynamics of violence, and the structure of criminal justice institutions such as police departments and prisons (Karstedt et al., 2011). Viewing emotions in their broader social and cultural context permits a fuller understanding of their role in the law and points the way toward a rich set of questions for future scholars in the field of law and emotion, several of which are discussed below.

Emotion and Social Norms

Emotions such as shame, fear, trust, and the desire for approval are intimately involved in the development, communication, and enforcement of the norms animating law. Legal scholars have engaged with the emotional aspects of norm-creation in a few discrete areas, notably on the topic of why and how we punish (see, e.g., Murphy, 2003; Dubber, 2006). But emotions are implicated in a wide array of basic social norm questions, such as the creation of familial norms, norms of respect for intellectual property, norms about the moral force of mortgage obligations (White, 2010), and questions of why citizens obey the law or feel themselves part of a polity (Deigh, 2000; Dubber, 2006; Gewirtzman, 2009).

Emotion Cultures

Law is permeated with implicit social and cultural expectations about the feeling and display of emotion (for discussion generally of emotion cultures, feeling norms, and display norms, see Hochschild, 1983; Thoits, 1989). These include, for example, expectations about who is capable of romantic love and therefore marriage (Calhoun, 2000) or about what rape victims or domestic violence victims ought to feel and how they ought to express their feelings (Schuster and Propen, 2011) or about what pregnant women ought to feel toward their unborn babies (Guthrie, 2008). The study of emotion cultures also encompasses the culture of particular legal institutions, such as the bench (Maroney, 2011a), the courtroom (Lynch and Haney, 2011) the law school classroom (Harris and Shultz, 1993), and the law firm (Levit and Linder, 2010).

Effects of Group Dynamics on the Emotions of Individuals

What effect does group participation have on the emotions of individual group members? For instance, does jury deliberation increase or decrease the emotional effect of various types of evidence on individual jurors? These questions are ripe for jury researchers.

The Unique Dynamics of Group-Level Emotion

Increasing empirical research is underway on group-level emotion, intergroup emotion, and emotional contagion (Parkinson et al., 2005: pp. 87–143). This research ought to be of enormous interest to jury researchers, as well as to those studying group decision-making in legal institutions more generally, and to those studying the effects of public opinion on legislation and other legal initiatives.

Emotion and Institutional Structure

Institutions are, inevitably, constructed in light of assumptions about emotional dynamics, and these assumptions should be illuminated and evaluated. Knowledge of emotional dynamics can be utilized to restructure incentive systems and construct more effective legal institutions. For example, Minow (2000) has examined the respective roles of divorce courts, mediation and arbitration tribunals, and truth and reconciliation commissions in channeling, educating, exacerbating, and responding to emotions. Ahmed and Braithwaite (2011) have investigated how institutional management of shame and pride affects bullying in the workplace.

Emotion and the Mobilization of Rights

Emotion theory can shed important light on how rights are conceived, how perceptions of fairness and unfairness arise, how political persuasion works (Westen, 2007; Krause, 2008), and what drives and sustains legal change and reform. Emotion can bind commitments to social and legal structures or provoke or sustain a challenge to those structures (Goodwin et al., 2001; Turner and Stets, 2005). Conversely, legal developments can create emotional momentum that leads to social change (see, e.g., Gould 2001, discussing the mobilizing effect of the US Supreme Court's decision in *Bowers v. Hardwick* (1986)).

Some Areas for Future Study

Underexplored Doctrines

These include First Amendment issues such as the regulation of offensive speech; the emotional dynamics animating the separation of powers doctrine; the role of emotional attachment to property in the measure of just compensation or in adverse possession doctrine; the role of trust in contract law, and assumptions about affective bonds undergirding the law of wills and trusts.

Underexplored Legal Actors

Studies of juries should move beyond the focus on individual jurors and take increasing account of the dynamics of the jury as a collective entity. The salutary trend toward studying judicial emotion should be expanded to include studies of how emotion affects decision-making by legislators, regulators, attorneys, and other legal actors.

Emotion and Persuasion

Emotion's role in rhetoric and persuasion is often dismissed as a form of manipulation or pandering, yet emotion plays an essential role in effective communication and persuasion. What role does, and should, emotion play in the persuasiveness of various forms of legal argument, including judicial opinions and dissents, the arguments of advocates, and jury deliberation?

Emotion and Legislation

In addition to studying legislators, scholars might focus on the relationship between emotion and legislation. For example, what is the appropriate role of emotion in providing an impetus for legislation? What is the role of legislation in acknowledging or giving voice to constituent emotion? (See, for example, Sanger's (2012) discussion of legislation requiring the provision of stillborn birth certificates.)

Strategies for Educating Emotion

In light of increasing evidence that institutions can be structured to promote a range of values and emotional attributes, debate about the structure and function of legal institutions should encompass the question of which values and attributes are worth promoting in particular contexts and how to do so.

Conclusion

The law offers an unparalleled opportunity for emotion researchers: a rich occasion to explore emotion as it operates in a complex set of institutions designed to reflect, channel, and educate human behavior. Legal theory and practice stand to benefit tremendously from this body of knowledge, and indeed, the legal system proceeds without this essential insight into human behavior at its peril, and to the detriment of those it serves. Legal doctrines and legal institutions too frequently rely on unexamined or demonstrably faulty assumptions about emotion and its effects on human behavior. Law and emotion scholarship has often focused on illuminating the role of emotion in law, which is an essential aspect of the project, but one that must be increasingly accompanied by interdisciplinary investigation, by debate about whether the disconnect between assumptions and evidence interferes with the administration of justice, and by concrete proposals for implementation and reform.

Law and Everyday Life

Abstract

Historically, law and everyday life have been defined in opposition to one another. Over the past century, the boundary separating law from everyday life has become blurred. Increasingly, socio-legal scholars understand law and everyday life to be mutually constituted in a dynamic and emergent process wherein law is produced and applied in the everyday domain of social action. At the same time, the practices, relationships, and meanings that make up the everyday are themselves, in part, constructed by law or legality.

Law and Everyday Life

Law and everyday life have been defined historically in opposition to one another. Everyday life has typically denoted that sphere of social action characterized by being familiar, routine, pragmatic, and particular: the world of work, play, family, and leisure. By contrast, law has been conceptualized as formal, timeless, general, and transcendent. In the context of this opposition, law was understood to radiate downward toward everyday life to resolve conflicts and impart order. Everyday relationships, interactions, and practices were thought to constitute the objects upon which law operated with varying degrees of success. Alexis De Tocqueville articulated such a view of law and the everyday life over 200 years ago:

> The language of the law thus becomes, in some measure, a vulgar tongue; the spirit of the law, which is produced in the schools and courts of justice, gradually penetrates their walls into the bosom of society, where it descends to the lowest classes, so that at last the whole people contract the habit and tastes of the judicial magistrate. (Tocqueville, 1959: pp. 2–20)

Over the past century, the boundary separating law from everyday life has become increasingly blurred. With the blurring of this boundary, the presumed direction of effect from law ('the schools and courts of justice') downward to 'society' has likewise been challenged. Increasingly, socio-legal scholars understand law and everyday life to be mutually constituted in a dynamic and emergent process wherein law is produced and applied in the everyday domain of social action. At the same time, the practices, relationships, and meanings that make up the everyday life are themselves, at least in part, constructed by law or legality.

Legal Realism: The Everyday Life of the Law

In the early twentieth century, a perspective called legal realism rejected the prevailing formalist perspective on law (*see* Legal Realism; Legal Formalism). Whereas legal formalism saw the law as having an internal logic that led to determinant outcomes, legal realism posited that law is more than the rules and pronouncements contained in judicial decisions or statutes. Legal realists understood that legal rules were not simply and mechanically applied by judges, lawyers, police, and regulators. They proposed to account for the gap between 'law on the books' and 'law in action,' that is, between the law as envisioned by its makers and law as it is actually enforced on a daily basis.

Oliver Wendell Holmes (1897), a distinguished jurist and philosopher of law, postulated that the life of the law is experience, not logic. The realist view of law as action and experience assumes that law has a life outside of legal texts and that the contours of law's life are shaped by the interests, and limited by the vision, of its agents. By studying the impediments to full enforcement of law, legal realists implicitly rejected de Tocqueville's assertion that the 'habits and tastes' of the magistrate inevitably penetrate into the bosom of society. In radiating outward, the law encounters myriad obstacles to its full and intended enforcement. The obstacles might include the bounded rationality, political, or economic interests, or even the biographical idiosyncrasies of legal agents. In short, in entering the realm of lived experience, legal rules are articulated within particular social and historical contexts that shape law's effects. This proposition authorized an examination of those contexts and constraints, thus creating an opening to the everyday in the study of law.

Law First Perspective

Legal realism – even while it acknowledged the life, and not merely the spirit of the law – assiduously maintained the boundary between the law and everyday life, retaining what has been called a 'law first' orientation (Sarat and Kearns, 1993). Even Holmes – after declaring the logic of law to be a myth – closes his essay 'The Path of the Law' (1897) with an invocation of law's universality and distance from everyday life: "The remoter and more general aspects of the law are those which give it universal interest. It is through them that you…connect your subject with the universe, and catch an echo of the whole, a glimpse of the unfathomable process, a hint of the universal law" (pp. 405, 406). The law may make its way in the world, but it still inhabits the lofty reaches of the universe. Moreover, the view that the law is distinct from the everyday underwrote the legal realists' conviction that the law could be used instrumentally to bring about progressive social reform.

Karl Llewellyn and E. Adamson Hoebel in their classic book *The Cheyenne Way* (1941) proposed that law performed a dual function in ordering everyday life. Frequently, the law's prescriptions operated beneath the level of notice or consciousness "to make [people] go round in more or less clear ways." In this regulative function, the law created routines and norms that structured people's practices and expectations. At times, however, the so-called drift of everyday life produced divergent interests, expectations, and norms that upset the orderliness of social life. Llewellyn and Hoebel referred to these instances as 'trouble cases' and proposed that a central function of the law is to process these cases to restore social order. 'Law,' they wrote, "exists for the event of breach of law and has a major portion of its essence in the doing of something about such a breach" (Llewellyn and Hoebel 1941: p. 20). How law responds to such breaches – how it selects cases of trouble, in what way it redresses these situations and with what consequences – ultimately comes to comprise the law. Accordingly, Llewellyn and Hoebel recommended empirical examination of the selection, processing, and resolution of 'trouble cases' as a way of elucidating and understanding the law. Research in this tradition focused on the everyday work of legal professionals, examining such processes as judicial decision making, prosecutorial discretion, or police arrest practice within specific organizational and political contexts.

When the everyday world is examined within this tradition, it is only at the boundary that separates law from society, in those settings where citizens brought their disputes, claims, and grievances to the attention of legal professionals. Social scientific research examined, for instance, the sorts of claims and awards made in small claims courts (Yngvesson and Hennessey, 1975), the advice given in lawyer's offices (Sarat and Felstiner, 1995), or police arrest discretion (Black, 1971). In short, the everyday was included in these analyses of law, only in those instances when its familiar routines broke down to the point where the law was mobilized to restore order, redress an injury, or protect a right.

In *The Common Place of Law* (1998), Ewick and Silbey point out the problem with the 'law first' approach.

> The most serious limitation of this institutionally centered law-first perspective is that, by reckoning the boundary of law to correspond neatly to its formal institutional boundary, we drastically narrow our vision. By focusing our scholarly gaze on exchanges across that boundary, we fail to ask how people go to that hypothesized boundary. We exclude from observation that which needs yet to be explained: how, where, and with what effect law is produced in and through common place social interactions within neighborhoods, workplaces, families, schools, community organizations and the like. (1998: p. 20)

Everyday Life versus the Law

This 'law first' perspective shifted somewhat as scholars began to consider normative systems that function as an alternative or precursor to law – such as custom or religion. Whereas legal realists depicted the law as intervening in social life to create and restore order, Paul Bohannon (1973) presented law as emerging out of customary practices. He claimed that law resulted from a double institutionalization of such practices. This process of formalization granted to custom a force and legitimacy that eventually led to law having a life and dynamic of its own. Hence, according to Bohannon, while law attains an existence apart from the everyday, its source lies within the social. Its relative independence did more than simply reflect custom; as a result of the restatement of the customary in the process of formalization, the law is 'always out of phase with society' (Bohannon 1973: p. 311). Bohannon did not see the gap between the legal and the social as a problem, but rather as a fertile source of change and growth: "It is the fertile dilemma of law that it must always be out of step with society; but that people always… attempt to reduce the lack of phase. Custom must either grow to fit the law or it must actively reject it; law must grow to fit the custom, or it must suppress it" (1973: p. 311). Thus law and everyday are located in different 'realms,' yet they are inextricably linked to one another.

The 'law first' perspective was also displaced in research that examined citizens' decisions to turn to the law. Studying the daily enforcement practices of legal agents revealed the extent to which most western legal systems are reactive, that is, rely on citizens to mobilize the law. Obviously, this is true in the case of civil law where citizens seek legal remedies for private disputes. It is also true in regard to criminal law, however. In a classic study of police arrest decisions, for instance, Donald Black (1971) found that approximately 87% of all police–citizen encounters were initiated by citizens either in the role of victims or witnesses. In mobilizing both civil and criminal law, citizens are thus responsible for shaping the number and type of cases that the law processes. Recognition of their crucial role in determining legal caseloads, shifted research toward the question of how citizens interpret situations and make the decision to turn to law.

In this tradition, Felstiner et al. (1980–1981) developed a model of the interpretive process that leads up to a citizen's decision to seek legal remedies. To begin with, problems and situations (potential 'trouble cases') are not self-evidently injurious or legal. Therefore, Felstiner et al. refer to the first stage in this process as 'naming,' or defining a situation or event as injurious. 'Blaming' refers to the identification of a party who is responsible for the problem. Finally, 'claiming' entails bringing the grievance or complaint to a third party (which may or may not be a legal body) to obtain remedy. Although the model postulates an individual decision maker, it stimulated interest in the cultural meanings and values that might compete with interpretations favoring legal action at any point in the process. It also suggested that the relationship between law and everyday life was uneven and variable. Certain kinds of issues – for instance, environmental harm – are resistant to being transformed into legal disputes; while others – automobile accidents – yield a much greater number of legal claims. In considering these matters, socio-legal research extended its analyses to the communities and cultures that exist beyond the legal arena and led to a greater appreciation of how everyday life becomes illegible or uninterpretable within the grid of law and legal categories.

Researchers in the law versus everyday life tradition were also particularly interested in those instances where the law interacted with alternative normative systems. Legal anthropologist Sally Falk Moore (1972) examined the relationship between law and custom in the context of delimited structured everyday interactions, or what she referred to as social fields. She defined social fields as patterns of relationship and interaction that are ongoing and which generate rules that coerce or induce compliance. While such fields are defined by their capacity to generate norms and customs, their boundaries are porous and thus they are susceptible to external norms, including the law. Because of this openness, Moore characterized social fields as 'semiautonomous.' Actors within these fields are constrained by legal norms but not determined by them. Like Bohannon, Moore further blurred the boundary between the two spheres by highlighting how they might mutually reinforce or undermine one another. Drawing from an analysis of the garment industry, Moore noted that union bosses routinely refrained from enforcing the law when the workload was heavy and overtime was needed. In exchange, the garment contractors would give gifts such as liquor and dresses. Something that looked like friendships emerged over time and became essential for the smooth functioning of the industry. Moore points out, however, that these informal exchange norms did not supersede the law. Even in relaxing labor laws that stipulated hours of work, the law was operating, although not as its framers intended. Even if the labor boss did not enforce the law, everyone understood that he could. The law empowered him; and the possibility of his exercising legal rules explained the pattern of gifts and fictive friendships. Moore thus summed up the ongoing interpenetration of law and custom: "A court or legislature can make custom law. A semi-autonomous field can make law its custom" (Moore, 1972: p. 79).

A similar relationship was described by Stewart Macaulay in a classic article entitled 'Non-contractual Relations in Business: A Preliminary Study' (1963). Macaulay found that law suits for breach of contract are relatively rare among businessmen. The paramount reason for this included the availability of effective nonlegal sanctions that operated within the business community, such as gossip, giving or withholding of advice, or expertise. But more importantly, the businessmen's reluctance to use the law in lieu of these alternatives was due to the mutual desirability of maintaining ongoing relationships and the sense that invoking formal law would interfere with that goal. Robert Ellickson found that neighboring cattle ranchers in California rarely invoked the law in disputes involving trespass. Like Macaulay's businessmen and Moore's garment contractors, the ranchers, according to Ellickson, do not want, or necessarily need, the law to achieve order.

Others examined the cultural and symbolic implications of resorting to law in the context of alternative normative realms. In her ethnography of a small Baptist community in Georgia, Carol Greenhouse found that the religious commitments of the members of this community tended to suppress disputes and steer members away from secular legal processes in the event that disputes did occur (1986). Their outright rejection of law, she wrote, "…is rooted in the logic of sacredness that obviates not only applications of human authority, but human authority itself" (p. 206). Robert Kidder (1990) studied other 'law-avoiding' societies – including the Amish and the Japanese – and similarly discovered, in each case, an incompatibility between the community's ideological or spiritual commitments and law.

The research on law avoidance thus served to correct the sense that law was paramount in ordering relationships in modern societies. By proposing that law is only one of variously competing normative orders available to citizens for achieving orderly relationships, this research further underscored the need for a serious consideration of everyday lives, relationships, and beliefs of citizens.

Although this research abandoned an exclusive or primary focus on formal law – considering informal community norms and practices as well – it continued to conceive of law and everyday life as distinct and relatively autonomous from one another. Indeed, by focusing on law avoidance, the relationship between the formal law and the informal norms of everyday life was depicted as not merely distinct but oppositional. Subsequent research and theory has challenged the idea that law and everyday life are autonomous or oppositional, suggesting instead that the two exist in a dynamic and mutually constitutive relationship.

Law in Everyday Life; Everyday Life in Law

In the last two decades of the twentieth century, socio-legal scholars began to examine everyday life not simply as an object of legal action or as a reservoir of potential legal cases but as a domain in which law circulates, is appropriated, invoked, resisted, and produced. This view of the law rejects the notion of law as a mere instrument to be used or avoided by citizens for achieving social or private ends. Law and the everyday are seen as mutually constitutive, that is, literally 'making up' each other in an ongoing dynamic process.

Barbara Yngvesson (1989) has argued that law is invented by citizens in local struggles over the meaning of fundamental cultural symbols such as 'community,' 'neighborhood,' or 'rights.' As citizens act on their understanding, law "emerges in the exchanges and the struggles of everyday people, in neighborhood fights and lovers' quarrels, in the framing of claims and complaints to the police, the court, neighborhood justice, and other agencies, and in the response to these agencies to such claims." (p. 1709)

Citizens do not, in other words, simply mobilize the police or go to court with their preconstituted legal cases. Before the formal legal apparatus has been invoked, the cases have been fashioned out of the popular legal culture circulating in everyday life. The results of that fashioning come to constitute what cases are processed, decided, and contested in formal legal settings. Rather than imagining law as existing apart from social relations, or conceiving of it as produced solely by groups of powerful lawmakers (such as legislatures), in this constitutive view, law is understood as emerging from the 'bottom up' as a continuing product of practical reason and action.

Of course, the shape and content of everyday life is fundamentally dependent upon law as well. Even when we act in

situations that seem devoid of legal meaning or involve a self-conscious avoidance of law, we do not escape the constitutive power of law. The law creates roles, relationships, and obligations. It 'names the world.' To routinely enact the roles of wife, doctor, or consumer, or any social role, tacitly implicates the law. In fact, the appearance of the routine, the familiar, and the quotidian is in no small measure a consequence of those unspoken legal meanings.

This view of law and everyday life would take issue with the conclusions of research, such as Macaulay's (1963) and Ellickson's (1991). In demonstrating the absence of law in the ongoing relationship between businessmen or cattle ranchers, this research fails to note that the very roles and relationships in which their subjects act are legal creations. Moreover, the concepts of private property or profit, for instance, draw upon legally produced and sanctioned meanings. As Sarat and Kearns (1993) have written, "one is apt to catch more than a fleeting glimpse of law's presence in the putatively alegal responses" (p. 47).

Recognizing the pervasive presence of law outside of formal institutional settings, Ewick and Silbey (1998) used the concept of legality to augment the concept of formal law. By legality, they refer to the meanings, sources of authority, and cultural practices that are commonly recognized as legal, regardless of who employs them or for what ends. In this rendering, people may invoke and enact legality in ways neither approved nor acknowledged by the law. Legality operates as both an interpretative framework and a set of resources with which and through which the social world (including that part known as the law) is constituted. In sum, they conceive legality as an emergent structure of social life that manifests itself in diverse places, including both formal institutional settings and the everyday lives of groups and communities.

Studying legality wherever it manifests itself has led to the broadening of subjects and sites of research. One example of research that has systematically explored the presence of law in everyday life is Hendrik Hartog's analysis (Hartog, 1993) of the eighteenth century diary of Abigail Bailey. Hartog's reading of Abigail Bailey's diary reveals how this woman, over the course of many years, struggled to make sense of her marriage, her husband's sexual abuse of their daughter, and their separation and eventual divorce, as well as her own religious beliefs regarding her duties as a wife and mother. Hartog demonstrates that although law is conspicuously absent from the diary, this narrative of personal tragedy and change is incomprehensible without reference to legal categories such as the prevailing law of coverture (a woman's loss of legal rights or personality upon marriage). Abigail Bailey's perception and assessment of her situation and her daughter's experiences, were conditioned upon her understanding of the legitimacy of a husband's desires and the priority of his rights. Because the law established a husband as a virtual sovereign within his family, it was difficult to question or oppose openly her husband's actions as inappropriate.

The recognition that law and everyday life are mutually constitutive has led to an interest in legal consciousness, ideology, and resistance (*see* Legal Culture and Legal Consciousness). In fact, some have argued that the fact that our glimpse of law in everyday life is 'fleeting' gets to the heart of law's power and to the power that law confers. John Brigham observes that "Law is hard to see unless it wants to be seen" (2009: p. 382). The reasons for this are twofold: First, professional legal actors benefit from a vision of law as esoteric and remote from daily life. More importantly, when law constitutes the contours of life without being implicated in doing so, it naturalizes the power and privilege it produces. According to Antonio Gramsci (1971) when law 'disappears' itself from daily life, its power becomes hegemonic. The key to the hegemonic power of law is the maintenance of what Gramsci called 'contradictory consciousness,' an experience of the world in which an unbridgeable chasm exists between the experience of everyday life in which people encounter the conditions of work and lived social relations and the official accounts of how things work. Hegemonic power operates not by top–down social control or the imposition of a single vision of the world, but by disqualifying the significance of everyday experience through reification, wherein historically specific processes and behaviors are 'misrecognized' as having a temporal and spatial transcendence.

The study of the hegemonic power of law has led to an interest in how the law is embedded in citizens' consciousness, how they imagine and 'enact' law. This would include not only how and when citizens mobilize formal law, but also how they may invoke, interpret, avoid, and deploy law and legal concepts in daily interactions even when no formal or official actors or rules are involved. Socio-legal scholars who have studied the legal consciousness of ordinary citizens have found evidence of such contradictory consciousness in which the internal connection between legality and particular experiences is severed in ways that insulate legal institutions from critique. The reified version of the world becomes the standard of objective reality against which the subjective, the concrete, and the immediate (the 'here and now-ness' of everyday life) are assessed and interpreted. Ewick and Silbey (1998), for instance, found that American citizens often locate legality in the legal rules and regulations that seem to produce effects independent of human action. One man they interviewed, explained why he failed to lodge a complaint of discrimination after having been paid less than others. He explained that his employer used 'a grading system' to determine salaries and there was nothing he could do. His injustice claim was thus thwarted by an impersonal metric that seemingly could not be challenged.

Yet, hegemony is never total. It is, rather, a "process of continuous creation which, given its massive scale, is bound to be uneven in the degree of legitimacy it commands and to leave some room for antagonistic cultural expressions to develop" (Adamson, 1983: p. 174). Indeed, within the contradictions of consciousness lie the possibilities for challenge and resistance.

For example, David Engel's study of the Education for All Handicapped Children Act of 1975 (Engel, 1993) rejects a traditional analysis that would have traced the ways in which this legislation unilaterally constrained or defined the educational experiences of children, the meaning of their physical conditions, or the interactions that occurred between parents and educators. Instead, he examines how this legislation and everyday life within this community are

interdependent and mutually shaped this social domain. At times, Engel notes, the law reinscribed 'commonsense' images of disability and difference, constituting the meaning and content of those social categories as they operated within the community. Even though the intended effect of the legislation was to challenge the community's perception of these students as different, – by mandating educational inclusion – the law's challenge to common prejudices was only partial. Engel observes, for instance, that in order to receive the benefits of educational inclusion guaranteed under this legislation, the law required an initial determination by educational experts that a child was different, in other words disabled or abnormal, and thus subject to the law's protection. He also shows that the operation of the law in marking differences did not itself go unchallenged. Parents resisted this requirement, with varying degrees of success, by rejecting the holistic term 'disabled' and insisting on more specific and limited descriptions of each child's condition (such as 'speech impairment' or 'cerebral palsy'). This sort of resistance was possible because the legislation did not simply reinstate existing authority relations. The statute, by prescribing parental involvement, made such challenges possible. The legal rights of handicapped children were not simply bestowed from above or asserted from below, but emerged as a product of a complex array of social relations – part legislation, part community conceptions of difference, part professional authority, and part parental desires for their children's inclusion.

Research such as Engel's illustrates that law's presence in everyday life, while a source of its hegemonic power, also exposes law to forms of resistance, subversion, and alteration. While much of this resistance is tactical and opportunistic, remaining as fleeting and ephemeral as the power it opposes, it may also take the form of an organized challenge. In their analysis of the development of the alternative birth movement, Beckett and Hoffman (2005) argue that the movement was paradoxically stimulated by the efforts of organized medicine to mobilize law to prevent the licensure of midwives. Having entered the discursive field, law – in particular that law that 'privileged' organized medicine – became available as a resource for challengers. "The fact that many legislators explained their decision to vote in favor of midwifery licensure in terms of the very categories that are thought to privilege medicine indicates that hegemony is indeed contestable and transformable. Cultural meanings, images, and associations are not fixed, but (somewhat) fluid; this fluidity is an important resource for movement activists resisting sociolegal hegemony" (p. 164).

Recognizing the fallibility and vulnerability of law that circulates in everyday life, Kitty Calavita (2001) claims that law can have deconstitutive effects, that is, it can undermine its own ideological categories. Analyzing the public rejection and ridicule of an Italian Supreme Court decision that overturned a rape conviction on the grounds that the alleged victim was wearing blue jeans (which the court assumed could not be taken off without cooperation by their wearer), she argues that law exposed its own 'ideological blunders' and the outmoded moral vision it endorses. She concludes that such deconstitutive events are more likely to occur during 'unsettled cultural periods' during which there are explicit challenges to entrenched ways of thinking and doing (Swidler, 1986: p. 273).

The fate of law and everyday life in such unsettled periods is the question examined by David Engel and Jaruwan S. Engel in *Tort, Custom and Karma: Globalization and Legal Consciousness in Thailand* (2010). They begin by asking "What happens to law in the lives of ordinary people when a society undergoes rapid change, economic development, and integration into global markets?"(p. 3). Based on in-depth interviews with 35 people from Chiangmai who had been injured as a result of the conduct of another person, the authors trace the transformation of legal culture and consciousness in contemporary Thailand as a result of globalization. They depict a situation in which both state and customary law are increasingly irrelevant and, in the case of state law, an illegitimate way of ordering social relations.

By the 1930s, Thailand had adopted a legal system that conformed to the model of a liberal legal state. Recognizing individual subjects, valuing neutrality in judging, and adopting written laws and opinions, this state law operated evenly across delimited spatial and temporal boundaries. Thailand also had a customary legality which was, by contrast, defined around the idea of sacred centers – located in the heart of family, village, and community – whose authority diminished as it radiated outward. This customary legality was animated by ideas of karma, spirits, fate, and collective harm, and it was based on these concepts that fault and remedy were defined. Despite their differences, state and customary legality were mutually reinforcing. Operating as a court of last resort to enforce decisions made at the local level, state law institutionalized, and thus reinforced, customary remedies. At the same time, state law derived its own legitimacy from its connections to customary legal forms.

This interlegality thus sustained the multiple legal orders. At the same time, as Engel and Engel's research demonstrates, such interlegality also exposed both legal orderings to a shared vulnerability. The rapid social changes in the late twentieth century meant that people work and travel far from their villages and thus from sacred centers and customary authority. Injuries are no longer interpreted within the discourse of malevolent spirits posing risks of collective harm and thus warranting collectively enforced remedies. Instead, injuries are considered karmic in origin and thus the responsibility of the injured person. Moreover, within this cosmology, to pursue legal compensation through state law is thought to be a delusion and a form of attachment that will only lead to further suffering. Thus the displacements of globalization have led to the individuation of injuries and a withering of both state and customary law, and with them the possibility of obtaining justice through legal means.

Conclusion

Socio-legal research on law and everyday life began by conceiving of the two spheres as relatively autonomous. Research in this tradition asserted the primacy of law in generating norms and stressed its regulative function in processing 'trouble cases' and restoring order to the everyday world. By the middle of the twentieth century, however, scholars began to question the distinctiveness of law and the everyday. Law not only performs a restorative function when

norms are violated, its categories and discourses constituted the order that is occasionally disrupted by trouble. People's identities and relationships are crafted out of legal ideas; the material world – including bodies – is a product of law. Thus, law was seen operating in the routine and the familiar; the personal and the intimate.

Eventually, scholars came to recognize that this constitutive relationship was mutual: as law circulated throughout social life, it too, was shaped by these encounters 'on the ground.' Persons and groups could reject, avoid, appropriate, translate, or simply ignore the law. In doing so, the content, form, and reach of law itself was produced. By exposing law's presence in everyday interactions, these insights generated considerable interest in the ways that collective actors could transform law (McCann, 1994) and how even relatively powerless persons could resist the force of law through their everyday acts of resistance (Sarat, 1988; Ewick and Silbey, 1998).

Most recently, scholars have noted the effects of globalization and neo-liberal governance on both the meaning of 'everyday life' and of 'law.' Globalization connotes a particular configuration of nation-state and capital such that the source and reach of power are extended to overcome both time and space. This means, among other things, that power can be exercised remotely and in such a way as to exceed the contours of ordinary life. Similarly, globalization challenges the idea of sovereignty and with it traditional notions of law. In many ways, globalization has thus disrupted not only the relationship between law and the everyday, it has destabilized the categories themselves. These developments suggest that it is not sufficient to simply state that there is a constitutive relationship between law and everyday life, without specifying the nature of the relationship or acknowledging that it can wither or be curtailed. As Engel and Engel observe, in an age of neo-liberal governance and globalization, "[T]he inactivity of law in the lives and consciousness of ordinary people may be its most important feature…" (2010: p. 161). What had been definitively fixed (initially, that law and the everyday are separate; subsequently, that they are mutually constitutive) is now seen to be empirically contingent. Although the lives of ordinary citizens may be suffused with law and legal accountability, other actors – such as transnational corporations – can move across and beyond legal jurisdictions, effectively floating free of both law and the everyday world on the ground. Thus, while the law may be 'all over' for some actors (Sarat, 1988) it is not evenly so, nor is it uniform across time and space. New research in the relationship between law and everyday life must, then, account for the absence as well as the presence of law in a globalized world.

This article replaces the previous edition article by N. Blomley, volume 12, pp. 8481–8485, © 2001, Elsevier Ltd.

Abstract

The article will overview changing theorizations of the relationships between law and geography, beginning with the 'regional' accounts of the early years of the twentieth century, where laws were seen as structured by geographic and environmental conditions. These are compared with the 'impact analyses' of mid-century, where law was seen as structuring space, and with a contemporary legal geography, where the relationship between space and law is seen as mutually constitutive, political, and socially consequential. Substantive empirical foci will include the regulation of public space and international immigration and border enforcement. It is suggested that this scholarship offers useful insights into a broader array of questions relating to law, social relations, power, and social space.

'Law and geography' should be defined as the analysis of the manner in which law, as a set of processes, texts, and practices, is shaped by the geographic dimensions of social and political life, and the ways in which the geography of social life is in turn structured by law. Defined thus, the systematic study of the relationship between law and geography has a long, although uneven, pedigree. Over the last century, scholars have defined both 'law' and 'space,' and the relationship between the two, in opposed ways, sequentially foregrounded space and then law. The first decade of the twenty-first century, however, has seen considerable interest in transcending the binary divide between law and space.

The article will overview changing theorizations of the relationships between law and geography, beginning with the 'regional' accounts of the early years of the twentieth century, where laws were seen as structured by geographic and environmental conditions. These are compared with the 'impact analyses' of the mid-twentieth century, where law was seen as structuring space, to contemporary debates in a self-defined legal geography, where the relationship between space and law is seen as mutually constitutive, political, and socially consequential. This scholarship offers useful insights into a broader array of questions relating to law, social relations, power, and social space.

Regional Studies of Law

The earliest 'legal geographies' were concerned with describing and explaining the regional diversity of legal systems. Eminent eighteenth-century scholars such as Montesquieu (1748/1949) could thus be classified as early 'legal geographers.' Regional studies of law, however, were to come into their own in the early years of the twentieth century, with the development of comparative law and the sociology of law. The American comparative legal scholar John Wigmore, in particular, undertook an extensive three-volume survey entitled *A Panorama of the World's Legal Systems* (1928). With Kocourek in 1918, he coedited a collection on legal evolution that included papers written by lawyers, sociologists, and geographers, which perhaps is the definitive summary of the regional field (Kocourek and Wigmore, 1918).

The central claim among these authors appears to be that spatial variations in law are a function of local environmental factors. For some, the latter is defined as the physical environment. Picard (1918), for example, points to variations in climate, soil, forest cover, and distance from the sea as important in explaining legal diversity: "All these and other variations of land and atmosphere show their traces in the jural system … Brazil and Russia, because they are different geographic regions, will therefore have many differences in law" (p. 170). In keeping with the assumptions of the day, other scholars point to 'race' as an explanatory factor in legal variation. Similar regional schools also seem to have developed in interwar France and Germany.

Impact Analysis

If regional studies read from geography to law, an influential paper by American geographer Whittlesey (1935) inverted this relationship in his call for the exploration, as the title put it, of the 'impress of effective central authority on the landscape.' Trade tariffs or embargoes, land tenure systems, and the regulation of resource exploitation were all identified as laws that result in 'landscape modification.' Thus, in understanding a particular region, geographers were urged to consider those 'phenomena engendered by political forces' (p. 97). The geographer's task, it seems, was now to focus on law's spatial 'impacts,' while taking law itself as an external 'given.'

Such a definition of the relation between law and geography (which Clark, 1989, terms 'impact analysis') proved influential until the late 1980s. The tendency was to treat space as a surface upon which laws instrumentally impact. For Wije (1990, pp. 26, 30), for example, "Law is a means of achieving social control by regulating behavior or by altering behavioral incentives while geography can study the spatial ramifications of this behavior. … Law can be considered as a geographic… variable."

Both traditions offer specific insights. A regional analysis is useful to the extent that it reminds us of the ways in which law, despite appearances of homogeneity, can in fact be different and diverse. In reminding nonlawyers of the undeniable importance of laws in social life and spatial forms and patterns,

impact analyses are also useful. We only need to reflect on the direct and indirect ways in which, for example, the urban landscape is a product of countless legal decisions, rulings, and mediations relating to real property, administrative law, and so on. Yet some commentators found these analyses partial and limited in terms of the ways in which they theorized law, space, and their interrelation (cf. Clark, 1989; Blomley, 1994).

Legal Geography

The 1990s, consequently, saw the emergence of a third school of legal-geographic inquiry that, in building upon but departing from the ideas discussed here, attempted to redefine both law and space; it also moved beyond the dualistic thinking that relates one to the other. The work of Gordon Clark, especially his *Judges and the Cities* (1985), and Nicholas Blomley, in his *Law, Space and the Geographies of Power* (1994), was important here. Identifying itself as 'legal geography,' this scholarship can be traced within geography, law, sociolegal studies, anthropology, and elsewhere. While far from unified, much of it drew from a set of emergent claims concerning law, space, and their mutual relationship. Essentially, legal geographers productively brought together parallel retheorizations of law and space.

First, in keeping with much recent scholarship, law itself was defined as more than a set of positive, external commands; it was to be understood as implicated in an array of social relationships. For example, law can produce many social and political effects, as it is able to define relationships, confer status, and selectively empower. This is important, given the reach of law in our lives, defined either formally (in the sense of statutes, judicial interpretation, etc.) or informally (the more messy, but no less important, legal sensibilities that we carry in our heads and express in our daily practices). As Twining (2000, p. 1) notes, law is omnipresent:

> One way of introducing students to the study of law is to ask them to read every word in a newspaper and to mark all the passages that they think deal with law or are "law-related" … Even those who adopt a narrow conception of law find it on every page … On the arts page, pornography, copyright, defamation, and other issues relating to freedom of expression arise along with licensing, charities law, taxation, and the ubiquitous contract. The advertisements are permeated with legal words and phrases. And so on through the paper.

Law can usefully be understood not only as a set of operative controls, but also as a repertoire of cultural and political meanings through which citizens can negotiate and interact with one another. Legal discourses offer a 'relatively plastic medium for refiguring the terms of past settlements over legitimate expectations and for expressing aspirations for new forms of entitlement' (McCann, 1994). These discourses were seen as important, shaping the ways in which people conceive of the political realm and their place within it. For some critical scholars, law was seen not as socially benign or neutral, but as confining and oppressive, naturalizing hierarchy and limiting progressive alternatives (Peller, 1985).

What, then, of space? In tandem with legal scholarship, the 'spatial turn' in social theory saw Marxist, feminist, and poststructuralist theory arguing that space was to be understood not as an objective, a priori phenomenon, but as both socially produced and socially constitutive (cf. Lefebvre, 1979). This, again, was significant, given the claim for the wide-ranging importance of space to social life, relations, and identities. An everyday activity, such as a visit to a shopping mall, includes spatial practices (such as the act of shopping), spatial representation (the advertisements and designs within the mall, often designed to conjure up images of other exotic places), place (or perhaps the absence thereof, given the ways in which corporate domination and mall design conjoin to produce 'placeless' spaces), and scale (marketing and distribution networks through which 'global' products are channeled to our local stores).

Such spaces are again not inert, but rather socially and politically consequential. Examples of the social and political dimensions of space can be traced at various levels of inquiry. For example, simple reflection reveals the ways in which interpersonal spatial categories such as 'near' and 'far' are not abstract concepts but socially contingent, as the concept of 'personal space' reveals, as well as being culturally diverse. However, the categories are also more complicated. The workings of racism, for example, depend in part upon spatial arrangements that place racialized groups identified as unlike 'us' at a spatial remove from those who we hold 'near and dear.'

Viewed thus, the retheorizations of both space and law would seem to have opened up considerable common ground. Both law and space are produced through social and political action. In other words, they are not transcendental, 'natural' categories. Law and space can be experienced at many different levels. Both are deeply representational, entailing stories, discourses, and images; in this way, they provide an important vocabulary for representing and organizing the world. Consider that which is evoked by concepts such as the 'Third World,' for example, or 'blind justice.' Both are also corporeal. Law is deeply concerned with the body – for example, the way that bodies are displayed (pornography, obscenity, etc.); what can be done to bodies (murder, rape, abortion, tattoos, etc.); and the movement, confinement, and control of bodies (e.g., through trespass, imprisonment, or capital punishment). The body is also spatially constituted and conceived – think of the different expectations concerning the comportment of men and women in public space, for example. Law and space are also material, beyond the body; that is, we experience both not only through representations but also in our encounters with material objects. Law is not only texts and words and images. It is also bullets, fences, prisons, 'For Sale' signs, doors, and windows. Similarly, space is made manifest and significant through, for example, the arrangement of chairs in a room, or the socially differentiated ways in which people set a table.

Separately, then, a considerable body of scholarship had argued for the respective significance of space and law along these lines. Yet, surprisingly, until the 1990s, there had been no systematic attempt to connect the two. This was the task that legal geography set itself, with the insistence that in doing so, we learned something new about law's work in the world. Social and political life, legal geographers argue, can be usefully thought of as simultaneously spatial and legal: "'law' and

'geography' do not name discrete factors that shape some third prelegal, aspatial entity called society. Rather the legal and the spatial are, in significant ways, aspects of each other …" (Delaney et al., 2001, p. xviii). If law and space, separately, are important to social life, then their combined effects are worth looking at. A shopping mall, for example, is simultaneously a space and a bundle of legal practices and discourses. So, for example, the mall's significance to constitutional rights of expression is not an abstract one: it is the fact that people enter and use a physical space that gives it practical relevance. But the space of the mall itself is legally constituted, reliant upon the workings of property, contract, and labor law, as well as zoning and other factors.

These insights, and their ramifications, have fed a growing body of literature. Special issues of journals include *Urban Geography* (11, 5, and 6, 1990), *Stanford Law Review* (48, 1996), *Journal of Historical Geography* (2000, 28), *Law/text/culture* (2005, 9), and *International Journal of Law in Context* (6, 3, 2010). Book-length overviews include Holder and Harrison (2003), Blomley et al. (2002), Sarat et al. (2003), Taylor (2006), Benda-Beckmann et al. (2009), and Braverman et al. (forthcoming). Useful overviews can be found in Blomley (2003, 2008), Manderson (2005), and Blank and Rosen-Zvi (2010).

Legal-geographic research has been conducted on a number of phenomena, including racism (Delaney, 1998), nationalism (Darian-Smith, 1995), property (Blomley, 1998, 2005; Graham, 2010), public space (Mitchell, 1996), climate change (Benson, 2010; Osofsky, 2009), globalization (Mahmud, 2007; Berman, 2002; Robertson, 2011), Israel and Palestine (Kedar, 2001; Braverman, 2009), and colonialism (Harris, 2008; Mawani, 2003). Generalizing about this diverse literature is not easy. While much is avowedly critical in orientation, some is more applied. Much of the work has been focused on particular case studies, making generalization more difficult. One possible distinction (Delaney, 2003) is that between 'Law-in-space' and 'Space-in-law.' The former concerns the ways in which law – statutes, judicial interpretations, the practice of legal officials, and so on – helps produce space. So legal actors, such as judges, can usefully be thought of as geographers, to the extent that their interpretations and edicts make space. Property is an obvious example: the spatial architectures of land ownership, both public and private, in which we all live and negotiate an everyday basis, have been made through generations of legal practice on the part of judges, surveyors, lawyers, police officers, municipal officials, and, of course, owners and nonowners.

Law in this sense does not 'impact' upon space but rather helps constitute it, to give it meaning and significance. This is not straightforward; it often entails complicated forms of interpretation and disagreement. Erbsen (2011) describes the multiple spaces that are produced by constitutional practice in the United States, arguing that many discrete problems on which scholars have focused – such as the rights of US military detainees abroad, the role of federal law on Indian reservations, and the extraterritorial reach of state law – reflect a deeper spatio-legal ambiguity in how the US Constitution allocates power over different kinds of spaces.

One very important way in which law produces space is through its designation of boundaries, marking distinctions between spaces (e.g., the public and private world) (Blandy and Sibley, 2010). This can be highly localized (e.g., property boundaries) or globalized (e.g., international law, state boundaries, etc.). These boundaries are said to be consequential:

> Boundaries *mean*. They signify, they differentiate, they unify the insides of the spaces that they mark. *What* they mean refers to constellations of social relational power. And the form that this meaning often takes – the meaning that social actors confer on lines and space – is *legal* meaning. How they mean is through the authoritative inscription of legal categories, or the projection of legal images and stories on to the material world of things (Delaney et al., 2001, p. xviii).

However, others have questioned the manner in which boundaries generate legal meaning, arguing for more nuanced and ambiguous reception processes (e.g., Blomley, 2005).

'Space-in-law,' conversely, attempts to come at the geographies of law from the other direction, tracing the ways in which legal practice and discourse are shot through with spatial tropes and metaphors. Legal actors frequently engage in spatial representation, being concerned with the delineation of zones, boundaries, and domains. When a judge designates a shopping center as private, from this perspective, she draws upon (and helps reproduce) a particularly consequential 'map' of the social world. When property rights are talked about in terms of autonomy, boundaries, and separation, we also rely upon a geographic set of metaphors.

These legal representations touch all aspects of legal life, including property, constitutional law, contract, crime, and intergovernmental law. Don Mitchell (1996), for example, outlines the ways in which judges and other legal actors help define the boundaries between public and private space in US cities, and regulate the activities that are deemed permissible in such spaces. This, he notes, has had particularly oppressive consequences for those people who effectively lack private space – the homeless. Legal action and interpretation in this sense can actively create certain spatial arrangements, practices, or representations. So, for example, David Delaney (1998) analyzes legal decisions concerning the legality of restrictive covenants in the United States, designed to exclude black residents from white neighborhoods. Necessarily, this entailed various construals of urban space by the judiciary. For Delaney, the effect of such apparently objective mappings was to position the judge as an active participant in the construction of ethnic spatial segregation. Housing covenants and similar approaches to restrict property ownership have been outlawed in the United States, through Shelley v. Kraemer and McGhee v. Sipes. The Supreme Court held that the creation and maintenance of private racial covenants resulted in a state action that violated federal law, in this case the Fourteenth Amendment of the US Constitution.

However, some see the analytical divide between law-in-space and space-in-law as increasingly confining, to the extent that it invites a restrictive view of the relationship between space and law. Rather than treating law and space as autonomous categories and then tracing the effect of one upon the other, both should be treated as recursively interrelated, it is argued. A 'legal' concept such as 'jurisdiction,' for example, is also

irreducibly spatial. The prison and the shopping mall are both 'spatial' and 'legal,' such that it is impossible to separate the one from the other. Some legal geographers argue that we need a new language that takes us beyond such dichotomies, allowing us to discern the reciprocal materializations and significations of law, space, society, and power. Delaney (2010) envisions the two coexisting as the 'nomosphere,' where law operates as a tool for 'world-making.' For Delaney, the nomosphere does not start from the spatial and move into the legal, but treats each as already there, intertwined in powerful and engrained ways. Such a view refuses a view of space as simply material, and of law as exclusively representational. The neologism usefully extends the metaphor of geographing to identify law as instantiating space. If law is instrumental in making space, space too provides an apparatus for law. Similarly, Blomley (2003) has argued for an attention to the 'splice,' a composite that is both space and law. We can see an attention to the recursivity of the spatio-legal in relation to scholarship that rethinks state borders and public space.

In a decade marked by proclamations to defend territory and sovereignty, border sites have become testing grounds for new legal instruments in security, exclusion, and the War on Terror at the opening of the twenty-first century. As a result, identifying borders as a theoretical site of inquiry takes legal geography seriously and problematizes 'the line' as embedded in a larger series of practices and policies. Rather than imagining borders as static edges, new scholarship is bridging law and geography to think about these spaces as relational sites where 'power may be extended through,' bringing the border to a whole set of new locations far from the edges of the nation-state (Allen, 2011). In doing so, these scholars extend the border beyond a place of transit and examine the multiplicity of laws and jurisdictions that coalesce at borders, on immigrant bodies, and far off the shorelines of the nation-state. The border, consequently, is not an inert, fixed line, but a fluid and moving zone, productive of, and constituted by, legal practices.

Scholars such as Mat Coleman couple immigration law with ethnography to consider the way that US immigration law enforcement influences individual mobility and what Stuart Elden has called "the spatial extent of sovereignty" (Elden, 2009). In Coleman's work on post-9/11 immigration enforcement in the US South, border enforcement has been relocated away from the edges of the nation-state, as the US Department of Homeland Security has deputized local law enforcement to serve as federal immigration agents (Coleman, 2005, 2009). Coleman documents border enforcement practices moving beyond the border, with a complicated set of laws that carry the border to the migrant's body. In this way, post-9/11 immigration law carves out a new space, a spontaneous border, through passport checks on buses and biometric data collection in small communities far from the edges of the nation-state. Dubbed the 'thousand little borders' approach to immigration control by legal scholar Huyen Pham (2004), the displacement of border-work creates borders wherever migrants and the state cross paths. Coleman suggests that both borders and law are in motion, and his work on two particular laws (287(g) referenda and the Secure Communities program) applies issues of law and jurisdiction to space and territory. In so doing, he importantly shows the way each is produced through the other – that immigration law and border security help, as Joe Painter puts it, to 'effectuate the territory' and in turn produce complex spaces of interlegality (Painter, 2010).

But how is this mobile border itself experienced? Alison Mountz explores moments of legal and spatial liminality as asylum seekers leave one state yet do not fully arrive in the territory of another. Refugees are consigned to an interstitial spatial-legal moment – a period marked by "waiting, limbo, disruption of life before and after and legal and jurisdictional ambiguity that inhibits access to rights and protections encoded in domestic and international law" (Mountz, 2011, p. 381). Her 2010 book, *Seeking Asylum: Human Smuggling and Bureaucracy at the Border*, looks at the challenges that arise when migrants leave home and wait in detention, secondary screenings, and administrative holding centers. Through case studies of the United States, Canada, and Australia, Mountz shows that the border is not simply moving, as in Coleman's United States, but also telescoping. She likens the experience to a 'long tunnel,' whereby asylum applicants are kept in an intermediary space between home and legal personhood (Mountz, 2010). Much like the long jetway greeting passengers at the end of a flight, the long tunnel assumes a new space between 'here' and 'there' – an exceptional space somehow outside the territory for the purposes of asylum.

Another example of the recursive nature of law and space can be seen in scholarship on public space (Layard, 2010). The sidewalk and the plaza are equally 'spatial' (entailing borders, representations of space, spatial practices, material objects, and bodies in motion) and 'legal' (implicating concepts and practices relating to citizenship, police powers, rights, privacy, etc.). Scholarship that is fully attentive to the complicated imbrication of the two offers particularly powerful insights. Take, for example, the work of Beckett and Herbert (2010) on the regulation of public space in Seattle. Eschewing generalized claims for regulation, they note the use of very particular spatial tactics of control and exclusion, tracing their development, reach, and effects. To control space, it seems, is to organize and materialize law. Another example comes from Blomley's (2011) work. He avoids discussion of 'public space' as an abstraction, focusing on the sidewalk as a particular site. Avoiding generalized claims concerning 'law' in the abstract, he focuses on those actors (judges, city engineers, etc.) who literally produce the sidewalk and govern and interpret its uses and functions. In so doing, he reveals a very particular (and overlooked) legal logic. Yet this is not simply a 'legal' account. He also traces the ways in which the space of the sidewalk, and its constituent parts and users, is visualized, ordered, and produced, in a constant tension between fixity and placement, on the one hand, and flow and circulation, on the other.

Legal geography offers important and valuable insights. Thinking of the legal (such as it relates to property or crime) in terms of space, or the spatial (such as a boundary or place) in terms of law, promises new and enriched insight. Understandings of both space and law are changed, and new questions posed. This is important in an analytical sense: if we are interested in how spatial arrangements are put together or sustained over time, recognizing the role of law is important, and it has an ethical and social justice dimension that scholars need to be attuned to. For better or worse, legal geographies have political

and moral effects. Designating the mall as 'private property' can close down certain possibilities. Yet workers, seeking to picket their employers within the mall, may also use a legal language of rights, freedom, and citizenship to challenge such geographies.

Law and Morality: A Continental European Perspective

Robert Alexy, Christian-Albrechts-Universität, Kiel, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The relation between law and morality is one of the main problems of legal philosophy. In a discussion that reaches back more than 2000 years, two positions have prevailed: positivism and nonpositivism. The main argument in favor of nonpositivism and against positivism is the claim of law to correctness. This claim implies that law has a dual nature, which comprises a real or authoritative dimension as well as an ideal or critical dimension. The dual nature of law is the basis for the Radbruch formula, which says, in its shortest form, that extreme injustice is not law.

Under the general rubric of the concept and nature of law, one of the most fundamental problems is the relation between law and morality. Two positions have competed for attention for over two millennia: positivism and nonpositivism.

Separation Thesis and Connection Thesis

All positivists defend the separation thesis. In its most general form, it says that there is no necessary connection between the law as it is and the law as it ought to be. Or, in a more precise formulation, it states that there is no necessary connection between legal validity or legal correctness, on the one hand, and moral merits or moral correctness, on the other. By contrast, all nonpositivists defend the connection thesis, which says that there is a necessary connection between legal validity or legal correctness, on the one hand, and moral merits or moral correctness, on the other (Alexy, 2008b, 284–5). This implies that in order to determine the concept and nature of law, all positivistic theories are confined to two elements, namely, authoritative issuance and social efficacy. The characterization of nonpositivistic theories includes a third element as well, correctness of content (Alexy, 2002a, 3–4).

Forms of Positivism and Nonpositivism

Which thesis, the separation thesis or the connection thesis, is more defensible? Both lend themselves to a variety of interpretations. The answer to our main question turns on these various interpretations.

Within positivism, the distinction between exclusive and inclusive legal positivism is the most important difference where the relation between law and morality is concerned. Exclusive positivism, as defended most prominently by Joseph Raz, maintains that morality is necessarily excluded from the concept of law (Raz, 2009, 47). Inclusive positivism, as defended, for instance, by Jules Coleman, says that morality is neither necessarily excluded nor necessarily included. The inclusion is declared to be a contingent or conventional matter turning on what the positive law in fact says (Coleman, 1996, 316). This implies that the relation between law and morality in both cases, that of inclusive positivism as well as that of exclusive positivism, is determined solely by what is authoritatively issued and socially efficacious, that is, by social facts. Inclusive positivism is a form of positivism because it claims that the initial decision in a particular legal system to include morality in the law is contingent or conventional (Alexy, 2012, 4). Nonpositivism argues not only–against exclusive positivism–that morality is not necessarily excluded, but also–against inclusive positivism–that it is necessarily included; nonpositivism is therefore contrary to both forms of positivism.

The differences within nonpositivism are no less important than the differences within positivism. Of special importance for the debate over the concept and nature of law are the differences that stem from different effects on legal validity that are attributable to moral defects. Nonpositivism can determine the effect on legal validity that stems from moral defects or demerits in three different ways. It might be the case that legal validity is lost in all cases, that legal validity is lost in some cases but not in others, or, finally, that legal validity is affected in no way at all (Alexy, 2008b, 287).

The first position, according to which every moral defect yields legal invalidity, is the most radical version of nonpositivism. This position might be characterized as 'exclusive nonpositivism' in order to express the idea that each and every moral defect precludes legal validity. With this, in cases of moral defects, it excludes social facts from the sources of law. Augustine gives us a classical statement of this view when he says that "a law that was not just would not seem to me to be a law" (Augustinus, 2006, 86). A recent example is Deryck Beyleveld and Roger Brownsword's thesis that "immoral rules are not legally valid" (Beyleveld and Brownsword, 2001, 76).

The radical counterpart of exclusive nonpositivism is superinclusive nonpositivism. Superinclusive nonpositivism goes to the other extreme. It maintains that legal validity is affected in no way whatever by moral defects. At first glance, this seems to be a version of positivism, not nonpositivism (Waldron, 1996, 1566). This first impression, however, is recognized as misleading as soon as one sees that there exist two different sorts of connection between law and morality: a classifying and a qualifying connection (Alexy, 2002a, 26). These two sorts of connection are distinguished by the effects of moral defects. The effect of a classifying connection is the loss of legal validity. By contrast, the effect of a qualifying connection is legal defectiveness, which does not, however, reach so far as to undermine legal validity. It does, however, create a legal obligation or at least an empowerment on the part of appellate courts to quash

unjust judgments of lower courts. Immanuel Kant's combination of the postulate of '[u]nconditional submission' (Kant, 1996, 506) to the positive law with the idea of a necessary subordination of the positive law to nonpositive law can be read as a version of superinclusive nonpositivism (Alexy, 2008b, 289; 2010, 176). The same is true of Aquinas' thesis that a tyrannical law is law but 'not law simpliciter' (Aquinas, 1962, 947), or, as John Finnis puts it, "not law in the focal sense of the term 'law'" (Finnis, 2011, 364).

The third version of nonpositivism, inclusive nonpositivism, is found between the extremes of exclusive nonpositivism and superinclusive nonpositivism. Inclusive nonpositivism claims neither that moral defects always undermine legal validity, as represented by exclusive nonpositivism, nor that they never do, as represented by superinclusive nonpositivism. It claims that moral defects undermine legal validity under some conditions but not under others.

Inclusive nonpositivism is given its most prominent expression in the Radbruch formula, which, in its most compressed form, runs as follows: Extreme injustice is not law (Radbruch, 2006, 7; Alexy, 2008a, 427–8). According to this formula, moral defects undermine legal validity if and only if the threshold of extreme injustice is transgressed. Injustice below this threshold is included in the concept of law as defective but valid law. This means that inclusive nonpositivism includes a considerable degree of positivity, that is to say, a commitment to what is authoritatively issued and socially efficacious. The nonpositivism of inclusive nonpositivism consists, first, in establishing an outermost border of law and, second, in qualifying immoral or unjust law as not only morally but also legally defective. The practical consequences of establishing an outermost border become evident when one looks at the application of the Radbruch formula by German courts after the defeat of National Socialism in 1945 and after the collapse of the German Democratic Republic in 1989 (Alexy, 2008a, 428–32). A practical consequence of qualifying immoral or unjust law as not only morally but also legally defective is that appellate courts acquire the possibility of quashing unjust judgments of lower courts owing to their legal defectiveness.

The Argument from Correctness

The existence of two forms of positivism and three forms of nonpositivism shows that the debate between positivism and nonpositivism concerns far more than a mere contest between two monolithic positions, often presented as the opposition of 'legal positivism' and 'natural law.' And this is not all. Things become even more complicated as soon as one takes account of the fact that not only positivism as well as nonpositivism are in themselves complex. Complexity is also manifest in the structure of arguments for and against the different forms of positivism and nonpositivism. The Archimedean point of this structure is the argument from correctness. All other arguments revolve around this center.

The argument from correctness says that individual legal norms and individual legal decisions as well as legal systems as a whole necessarily lay claim to correctness. Ronald Dworkin has objected that the question of whether the representatives of law raise any claims is a question of fact, and not a question of necessity (Dworkin, 2006, 200). This objection can be rejected if it is possible to show that the claim to correctness is necessarily implicit in law, quite apart from the intentions of its representatives. Here the idea is to show that the explicit negation of the claim of correctness leads to a contradiction (Alexy, 2002a, 35–9). An example is the fictitious first article of a constitution that reads: X is a sovereign, federal, and unjust republic. This article is somehow absurd. The absurdity stems from a contradiction between what is implicitly claimed in framing a constitution, namely, that it be just, and what is explicitly declared, namely, that it is unjust. Now justice counts as a special case of correctness, for justice is nothing other than correct distribution and compensation. Therefore, the contradiction in our example is not only a contradiction with respect to the dichotomy of just and unjust but also a contradiction with respect to the dichotomy of correct and incorrect.

What is more in the aforementioned example of the fictitious first article of a constitution, the contradiction there between what is explicit and what is implicit is necessary. It could be avoided only if one were to abandon the implicit claim. But to do this would represent the transition from a legal system to naked power relations (Alexy, 1998, 213–4). Thus, our example shows that law and the claim to correctness are connected not only by contingent, prudential reasons, but also – and this goes a good bit further – by reasons necessary in nature. This connection is by no means confined to such fundamental acts as framing a constitution. It is present everywhere in the legal system, and may be illustrated by the absurdity found in decisions such as the following: The accused is sentenced to life imprisonment, which is an incorrect interpretation of prevailing law.

In order to establish a necessary connection between law and morality, it is not enough that the claim to correctness be necessarily raised by law. Over and above this, it is necessary that its content necessarily refer to morality.

The claim of law to correctness would not necessarily refer to morality if it were possible that it refer exclusively to social facts, that is, to what has been authoritatively issued and is socially efficacious. A claim with this content would count as a purely positivistic claim to correctness. Hard cases, however, illustrate that the positivistic interpretation of the correctness argument gives rise to serious problems. Hard cases occur when the positive law – that is, the authoritative or source-based reasons – allows for more than one decision. The decision to be made in such an 'open' sphere is a decision on a normative matter that cannot be based on standards of positive law, for if it could be based on such standards, it would not be a decision in an 'open' sphere. If it is to be based on any standards at all – that is, if it is not to be a merely arbitrary decision, a decision that would contradict the claim to correctness – it must be based on other normative standards. Legal decisions regularly concern questions of distribution and compensation. Questions of correct distribution and compensation are questions of justice. Questions of justice, however, are moral questions. In this way, the open texture of law, taken together with the nature of legal questions, implies that the claim to correctness raised in legal decision-making necessarily refers not only to authoritative or source-based reasons but also to moral reasons. This implies that the claim to correctness necessarily raised in law leads to a necessary inclusion of morality in law (Alexy, 2007, 49–50).

The Dual Nature of Law

Hans Kelsen has argued against nonpositivism that it presupposes "an absolute morality, that is to say, a morality that is valid everywhere and at all times" (Kelsen, 1967, 68 trans. alt), and, Kelsen goes on, no such absolute morality exists. One might call this the 'argument from relativism' (Alexy, 2002a, 53–5). The question of whether Kelsen's objection based on relativism is cogent is a question of interpretation. If one understands the objection as saying that there is no instance in which only one correct moral answer can be given, then the objection fails. There are cases of severe interference with human rights in which only one moral answer is correct or true, namely, that the interference violates human rights and is, for that reason, morally wrong (Alexy, 2012, 8–13). The existence of such cases suffices as an epistemological or meta-ethical basis of nonpositivism. If, however, one interprets Kelsen's objection as saying that there exist a number of cases, even a considerable number, in which 'reasonable disagreement' (Rawls, 1993, 55) about what is morally right or wrong is possible, then Kelsen's argument is based on a correct epistemological or meta-ethical thesis, but, and this is the point, it would then no longer suffice as an argument against nonpositivism. Nonpositivism is compatible with reasonable disagreement if it is possible to arrive at an approximation to truth or correctness in discourse and if there are at least some cases in which only one moral answer is right, that is, in which reasonable disagreement is not possible. Approximation to truth or correctness is possible because rational practical discourse is possible, and there are cases in which only one moral answer is possible for the reason that other results in these cases are discursively impossible – as, for instance, the legal status of a slave or the abolition of religious freedom (Alexy, 1989, 187–208).

The existence of reasonable disagreement means that there are a considerable number of social problems that cannot be resolved by moral argument alone. One might call this the 'problem of practical knowledge'. The problem of practical knowledge can be resolved only by means of legally regulated procedures that guarantee a decision. This is the step from morality to positive law, as described, for instance, by Kant (Kant, 1996, 456). What is more, the problem of practical knowledge is not the only problem that can be resolved only by means of positive law. A second problem is the problem of enforcement. If it is possible to violate the law without running any risk, and if some take advantage of this possibility, then compliance with the regulation is no longer assured. In short, procedures that provide for the enforcement of law are necessary. In addition, there is the problem of organization. A modern society can be effectively organized only by means of positive law.

The need to solve these three problems and, therefore, the necessity of positivity, that is, of authoritative issuance and social efficacy, stems from the moral requirements of avoiding the costs of anarchy and civil war and assuring the advantages stemming from social coordination and cooperation. As moral reasons, these reasons are elements of the content of the claim of law to correctness. This implies that the claim of law to correctness qua claim to moral correctness necessarily comprises elements of positivity. This is not to say, however, that the claim to correctness comprises solely elements of positivity. This is the mistake of superinclusive nonpositivism. The claim to substantial correctness – that is, first and foremost, the claim to justice – does not disappear once law is institutionalized. It lives on in the law. For this reason, one has to distinguish two stages or levels of correctness: first-order correctness and second-order correctness.

First-order correctness concerns justice as such. Second-order correctness is more comprehensive. It refers both to justice and to positivity. Justice represents the ideal or critical dimension of law, positivity its real, factual, or institutional side. The claim of law to correctness qua second-order claim unites the real and ideal dimensions of law. It is an expression of the dual nature of law (Alexy, 2010, 173–4).

The dual nature of law implies that law necessarily comprises two principles: the principle of justice and the principle of legal certainty. The principle of legal certainty is a formal principle. It requires a commitment to what is authoritatively issued and socially efficacious. The principle of justice is a material or substantive principle. It requires that the decision be morally correct. These two principles, as is the case with principles generally, may collide, and they often do. Neither can ever supplant the other completely, that is to say, in all cases. On the contrary, the dual nature of law demands that they be seen in correct proportion to each other. This, in turn, can only be achieved by balancing. The idea of an outermost border of law is a result of such balancing, that is, of balancing the principles of legal certainty and justice.

Outermost Border

The Radbruch formula that, in its shortest form, says that extreme injustice is not law is the classical expression of the idea of an outermost border of law (Radbruch, 2006, 7; Alexy, 2008a, 428). This formula represents, first and foremost, a rejection of the positivistic thesis that 'any kind of content might be law' (Kelsen, 1967, 198). Kelsen illustrates this thesis with the following remark: "According to the law of totalitarian states, the government is empowered to confine in concentration camps persons with rejected convictions, religion, or race and to force them to do any sort of work whatever, even to kill them" (Kelsen, 1967, 40, trans. altered). Killing persons in concentration camps for reasons of rejected convictions, religion, or race is a clear case of extreme injustice. Therefore, according to the Radbruch formula, norms that empower legal officials to do such things cannot be valid law. From the positivistic point of view, the situation is different. If these norms have been authoritatively issued and are socially efficacious, they are valid law. This is also true of inclusive positivism in instances where the positive law does not actually refer, in a socially efficacious way, to moral principles that exclude the killings. From the nonpositivistic point of view, everything depends on balancing the principles of legal certainty and justice. The principle of legal certainty stands for the view that the norm in Kelsen's example is legally valid, the principle of justice stands for the opposite result. The determination arrived at by balancing essentially depends on the intensity of interference with each of the colliding principles (Alexy, 2002b, 102). Not to conceive of the norm in question as invalid would count as an extremely intensive

interference with the principle of justice, for justice comprises human rights, and the interference with human rights in Kelsen's example is extreme. On the other hand, the loss in legal certainty if one were to conceive the norm as invalid would be quite limited. Even in totalitarian states, a great number of norms do not exceed the threshold of extreme injustice. Thus, the result of balancing is determined, and this result reflects precisely the Radbruch formula, that is to say, inclusive nonpositivism as defined by the formula. By contrast, superinclusive nonpositivism as well as exclusive nonpositivism must fail. Superinclusive nonpositivism fails, for it gives too little weight to justice, and exclusive nonpositivism fails, for it gives too little weight to legal certainty.

Participant and Observer

This justification of the Radbruch formula, it might be objected, is flawed on the ground that it is based on normative arguments, namely, the principles of justice and legal certainty. The question of the nature of law, the objection continues, concerns what law is, and what a thing is cannot be established by means of normative arguments (Raz, 1996, 7; Marmor, 2005, 778).

To reply to this objection, the distinction between the observer's perspective and the participant's perspective is fundamental (Alexy, 2002a, 25). An observer poses questions and adduces arguments on behalf of a position that reflects the way in which legal questions are actually decided in a legal system, whereas the participant poses questions and adduces arguments with an eye to what he deems to be the correct answer to the legal question at hand. The observer's perspective is defined by the question 'How are legal decisions actually made?' the participant's by the question 'What is the correct legal answer?'

Positivism reflects quite well the observer's perspective (Alexy, 2002a, 27–35). From this perspective, what the law is depends exclusively on what has actually been issued and is socially efficacious. By contrast, the participant's perspective presupposes nonpositivism. For a participant, the law is what it is correctly taken to be. What it is correctly taken to be depends, however, not only on social facts but also on moral reasons. In this way, normative arguments make their way into what the law is as soon as the participant's perspective is taken up. What is more, this perspective must be taken up – for law is possible without observers but not without participants.

Law and Morality: An Analytical Perspective

Tom Campbell, Charles Sturt University, Kingston, ACT, Australia

Abstract

Noting the similarities in content, form, and function between law and morality, the article examines significant differences between these two systems of normative social order. Having distinguished positive and critical morality, the article discusses whether (1) law ought to incorporate the positive morality of the citizens of that jurisdiction, (2) the critical moral principles that we adopt to criticize positive morality ought to be the same as those we use to criticize law, and (3) the role of human rights ought to keep law within morally acceptable bounds. This involves discussing the theoretical disagreements between legal positivism and natural law theory in terms of the 'separability thesis,' and touches on the controversial role of human rights as an essential moral minimum for valid law.

As complementary and yet partly competing systems of normative social order, law and morality have much in common and much to distinguish them. In content, form, and social function, law and morality exhibit similar features that can not only be mutually supportive but also generate social and political conflict, particularly in large states characterized by moral pluralism and constant social change.

There is substantial overlap in the content of the moral and legal norms of all societies, and law may readily be seen as both an expression of, and an influence on, a society's morality. Judges are normally expected to have regard to moral considerations when interpreting law, and, in many democratic countries, judges have power to override legislation that conflicts with those basic moral rights, such as freedom of expression, which are enshrined in the constitution of their polity. Further, legislatures are expected to make law in the light of the moral beliefs of the population. Conversely, the established law of a country has some effect on what its inhabitants regard as morally right and wrong by reinforcing and altering behavioral expectations.

Moreover, legal systems depend, in varying degrees, on securing the conformity of citizens to their requirements, which in turn depends, in part, on satisfying their moral expectations as well as their self-interest. In turn, the moral constraints that citizens impose on each other and on themselves through the informal processes of social approval and disapproval are crucially reinforced by the sanctions of criminal law and the remedies for such matters as breach of contract and negligently causing harm to others.

On account of their overlapping social functions, legal and moral discourse shares a whole range of basic concepts. Justice, fairness, rights, utility, equality, and freedom are the common vocabulary of both normative systems, which suggests that moral and legal obligations cannot always be clearly distinguished, and explains why in less developed societies there is little or no institutional divide in their normative structure between law and morality.

These commonalities and interactions of law and morality must be kept in mind when examining attempts to distinguish law and morals. They suggest that law and morality are parts of a wider system of normative order arising out of the elements of conflict and coordination that characterize human society. That said, there are important differences between law and morality that call for analysis, explanation, and evaluation. In particular, there is a recurrent and ongoing tension between the law of authoritarian states and the morality of oppressed majorities and between the law of democratic states and the morality of politically excluded minorities. Conceptualizing and explaining these conflicts and examining how they ought to be resolved are important themes in the social and behavioral sciences.

Critical and Positive Morality

Focusing on evident differences between law and morality, several key variables emerge: (1) law is *mandatory*, usually coercive, whereas morality is voluntary and often unenforceable; (2) law is an *institutionalized* system of norms, with specialized officials and procedures, whereas morality is individualistic, informal, and diffuse in its operation (MacCormick, 2007); (3) law is *public* and associated with the state, whereas morality is *private* and a matter for the individual to determine for herself; (4) law gives a significance to *precedents* and *sources* more than is the case with morality; and (5) laws may be *unjust*, but there is something incongruous in the notion of an unjust moral principle.

Some of these variables can be analyzed by distinguishing between two senses of 'morality.' The first sense refers to those norms of conduct that are generally observed and routinely used to criticize conduct in a given social group. This is sometimes called 'customary' or 'positive' morality (Austin, 1954: p. 122).

The second sense of 'morality' relates to the activity of criticizing and evaluating, from an external point of view, the norms and practices that make up both positive morality and the law of a society. It is this 'critical' morality (Hart, 1961: pp. 176–180), in which the content and form of positive moralities and actual legal systems are assessed morally, that gives rise to some of the perceived differences between law and morality. This happens where individuals and groups adopt a critical normative approach to the form and content of laws and legal systems. One of these differences is that critical morality is a matter of personal moral opinion (and cannot therefore be

coerced or forced on others), while the form and content of law (and indeed of positive morality) are matters of empirical fact. Critical morality may be contrasted with both legal and positive moral systems of norms, with law and positive morality sharing the characteristics that typify ongoing cultural structures and critical morality standing outside and above these phenomena. One contentious issue that arises here is whether, from the moral point of view, a person's critical morality takes precedence over their assumed moral obligation to obey the law. Precisely what that moral point of view may be is a controversial issue within moral philosophy, but we may take it to be the point of view that seeks to determine the ultimate criteria for assessing the worth of human conduct from an impartial or universal perspective (Baier, 1958).

Having distinguished positive and critical morality, we can frame the questions that arise in relation to law and morality in a more sophisticated way. Thus we may raise, as a matter of critical morality, (1) whether law ought to incorporate the positive morality of the citizens of that jurisdiction, (2) whether the critical moral principles that we adopt to criticize positive morality ought to be the same as those we use to criticize law, and (3) whether there is such a thing as 'critical law,' in contrast to 'positive law,' similar to the distinction between critical and positive morality, as most natural law theorists contend.

Legal Positivism and Natural Law

The relationships between law and morality have long been prime sites for the articulation of competing legal philosophies, particularly classical natural law and legal positivist approaches to the understanding and evaluation of law and legal systems. However, as we have seen, the relationships involved are varied in type and substance, and it is by no means clear that the traditional packages of theses associated with the classical theories still hang together. Indeed, there is a real prospect for conceptual realignments that render some of the historical debates on law and morality outmoded.

Legal positivism, which received its classical formulation in the work of Jeremy Bentham (1748–1832) and John Austin (1790–1859), emphasizes the contrasts between law and morality, and the political subordination of morals to the will of the sovereign (Austin, 1954). Following on from Hobbes' analysis of political authority, which he based on the requirements of mutual survival in a predatory social world, the state is seen as imposing a morally arbitrary rule of commands so as to secure peace between warring factions, religions, and moralities. This characteristically modern theory of the state replaced the medieval European synthesis of government, religion, and morality that received its classical formulation in the *Summa Theologica* of Thomas Aquinas, whose definition of law as "a rational ordering of things which concern the common good; promulgated by whoever is charge with care of the community" (Aquinas, 1966: Art. 4) sums up the fusion of law and morality in the natural law tradition.

Austin, through whose work legal positivism became the reigning orthodoxy in nineteenth century Anglo-American legal theory, presents his position in a series of definitions designed to identify actual or 'positive' (in the sense of observable) law in empirical terms, such as commands, sanctions, and habitual obedience. Law is defined as the general commands of a sovereign, that is, the person or group that is habitually obeyed in a certain territory and does not himself habitually obey anyone else. A command is the expression of a wish relating to the conduct of another and it is backed by threats of force, with the legal obligation being the likelihood that failure to comply with a command will be followed by the imposition of sanctions. Each state has one such sovereign (which may comprise an individual or a collectivity) who is at the giving (but not the receiving) end of such commands. The existence of this unitary sovereign is the core of the classical positivist analysis of the modern sovereign state.

It is a defining feature of this version of legal positivism that there is no necessary connection between law and morality (Hart, 1961: p. 181). The nature of the necessity embedded in the classical positivist separation of law and morality is based intellectually on Hume's distinction between 'is' (statements about what is and is not the case) and 'ought' (statements about what ought or ought not to be the case). In Austin's ringing words, "the existence of law is one thing, its goodness or badness another" (Austin, 1954: p. 184). Legal positivists insist that it is possible to separate out the description of law from our moral evaluation and criticism of that law: legal argument is not moral argument, legal authority is not moral authority, and a law is a law whether it is just or unjust, or good or evil. All this applies only to what is called 'positive law,' that is, the law as it is actually applied in human societies; but legal positivists contend that, strictly speaking, this is the only genuine law that exists.

Such a dichotomy depends on our capacity to identify law in an empirical manner, and this Austin does with his analysis of law as the command of a political sovereign. In the terminology of a more recent and equally famous legal positivist, H.L.A. Hart, the law of a jurisdiction can be identified by means of its 'rule of recognition' (Hart, 1961: pp. 92–93), which lays down the criteria used by legal officials to determine legal 'validity,' (i.e., what is and is not part of the law of that particular jurisdiction). In Austin's case, that rule identifies the commands of the political sovereign, the person or body that is habitually obeyed in a particular location, as the criterion that is necessary and sufficient for the determination of legal validity.

A similar approach is taken by the classical legal positivists to positive morality. The rules of conduct, which are widely followed in a given society and are backed by the sanctions of public approval and disapproval, are seen as a distinct system of identifiable moral norms analogous to positive law, although always overlapping with the positive laws of the same society in terms of form and content. Both of these positive systems are distinguished from 'natural law,' a term that Austin applies to what is actually morally right and wrong in human conduct, which he himself, following Bentham, takes to be the utilitarian standard of acting or refraining from acting so as to maximize human pleasure and minimize human pain. While such natural laws can be regarded, in positivist terms, as the commands of the ultimate sovereign – namely, God – Austin, and legal positivists generally, draw on utility as the basis for their critique of positive law and not as a test of legal validity. The classical natural law position, in contrast, is that knowledge of right and wrong as manifest in God's law, or discovered

through human reason or conscience, plays an essential part in the identification and understanding of all the positive laws that generate moral obligations.

For some natural lawyers, this means that there can be no such thing as an 'unjust law,' so that if a positive law is morally unjust, then it cannot be a genuine law. However, John Finnis, currently the most influential natural law theorist in the classical tradition, rejects this analysis and sees natural law theory as presenting the role of positive law as a social institution that is necessary to give concrete application to the general moral principles that derive from the idea of human flourishing (Finnis, 1980/2011). Other contemporary natural law theorists make the stronger contention that, while individual laws may or may not be just, the idea of law, as distinct from the content of particular laws, is necessarily connected to justice, for law as an institution must not only claim to be just but also seek to be so, otherwise it could not be a legal system (Beyleveld and Brownsword, 1989; Raz, 2009: p. 4).

A crucial matter of interpretation at this point is whether the role of morality in both classical approaches is an exemplar of critical or of positive morality. In the case of legal positivism, there seems no doubt that the utilitarian morality used to assess legal systems is a critical morality. Indeed, Bentham calls this activity 'censorial jurisprudence.' In the case of natural law theory, the situation is less clear because the moral methodology of natural law theory concerns 'nature' this includes human behavior, particularly normative behavior, which is conduct that involves the control of natural appetites in a way that makes social life and individual spiritual development possible. In effect, this means that universal positive morality has a key evidential role in determining what is in accordance with right reason. However, classical natural law theory often presents as a critical morality, and modern natural law theories, which are standardly uncoupled from theological backgrounds or moral deference to what is in accordance with nature, hold that it is a critical morality, albeit one that is central to the very idea of law (Simmonds, 2007).

Thus, some current understandings of both the natural law and legal positivist traditions appear to share the view that their role is to provide a moral critique of positive law, the remaining differences between them being about what sort of critical morality should feature in that critique. Legal positivists tend to adopt a utilitarian morality, and natural lawyers hold to a more communitarian morality focusing on human nature and the common good. A recent example of this latter position is the program for revitalization put forward by Robin West, who, drawing on the work of John Finnis and Martha Nussbaum (2001), calls for the adoption of a liberal and progressive natural law theory that recognizes that "Our happiness, our well-being, our capabilities, our flourishing, our functioning, and even our much maligned pleasure, cannot be reduced to the sum of the utilities we seek" (West, 2011: p. 44). Another question remains, however: how is it that the preferred critical morality does or should find its way into the content and practice of positive law.

All this does not mean, however, that modern versions of the classical theories are simply presenting competing schemes of critical morality with the utilitarianism of legal positivism pitted against secular versions of naturalism. Indeed, both approaches have outgrown their original moral affiliations. Exactly what is now at stake between the two approaches is best explained by reference to more recent controversies over what is called 'the separability thesis.'

Separation and Separability

With the introduction of Hart's rule of recognition, the classical debate about law and morality has come to be formulated in terms of what is known as the 'separability thesis.' This goes beyond the positivist idea that real law can always be traced to social sources, (e.g., commands, enactments, or court decisions) and takes us to the idea of a 'rule of recognition' that gives the official criteria for identifying those social sources by which norms and principles are 'recognized' as legal norms or principles.

The separability thesis, as formulated by Jules Coleman (1989), is the view that a rule of recognition need not include moral criteria, such as justice or utility, but can consist entirely of empirical identifiables, such as human commands, court decisions, or legislative enactments. Because this thesis possibility is compatible with all actual rules of recognition, including moral criteria as a matter of empirical fact, Coleman's minimalist form of legal positivism is compatible with what is called 'soft' (Hart, 1994, Postscript) or sometimes 'inclusive' legal positivism (Waluchow, 1994). This contrasts with the 'hard' or 'exclusive' variety of legal positivism, which admits only nonmoral criteria into anything that counts as criteria of validity in a rule of recognition. According to soft or inclusive legal positivism, it is a contingent matter how far a legal system officially incorporates moral considerations into its criteria of legal validity through the social practices that constitute lawmaking. This view is still regarded as positivist because it requires that morality enters into legal reasoning through an empirically identifiable rule of recognition that licenses this practice. Hard positivism also accepts that moral criteria are, and indeed ought to be, utilized in lawmaking through legislation, but insists that what makes that morality or anything else into law is its adoption by lawmakers authorized by a rule of recognition. The difference between soft and hard legal positivism thus comes down to whether or not legal officials, such as judges, are, in their jurisdiction, authorized to make law through the direct application of their own moral views. Important empirical issues then arise for social science as to whose morality finds its way into the law, and how far the morality within the law stems from legislative rather than judicial activity.

Viewed as a descriptive thesis, inclusive legal positivism is clearly superior as all legal systems enable some role for moral judgments in the adjudication that determines legal validity. Common-law systems permit judicial development of law in the light of broad moral principles, albeit subject to the theoretical right of legislators to amend the common law. Many legal systems incorporate a bill of rights with general moral principles that courts are obliged to interpret, something that includes some reference to the moral preferences of those who give concrete application to such vague moral standards as equality and freedom. This seems to accord more with a natural law approach, since it involves using what are perceived to be fundamental moral rights at a point where law and morality become inseparable (Dworkin, 1996).

The moral criteria in actual rules of recognition often serve to incorporate within law the customary or positive morality, or some identified aspect of it, rather than the personal or critical moral judgments of judges and other officials. This may be regarded as upholding what are regarded as reasonable expectations. However, since in modern complex societies there is seldom any indisputable agreed content to positive morality on almost any topic, in effect inclusive legal positivism legitimates the use of critical moral judgment in the process of adjudication, which in turn facilitates the impact of the political and self-interested views of judges. For the positivist to claim that there is a conceivable society in which this is the case is a relatively minor conceptual point to make about law and morality.

The retreat into soft, or inclusive, positivism is therefore explicable, especially as legal positivists have historically placed great weight on providing a descriptive theory of all developed legal systems. However, legal positivism can be understood in a more normative light as an approach that is seeking to establish a conception of a 'good' system of law, thus turning the separability thesis into a prescriptive claim that rules of recognition should not include moral terms that cannot be put into practice requiring moral judgments about what they require by way of legally required conduct. Hard, or exclusive, positivism may be viewed as a more or less disguised prescription that is recommending that a rule of recognition ought not to include moral criteria and that all positive law should be framed in such a way that it can be understood and applied without recourse to the moral opinions of citizens or judges (MacCormick, 1989; Campbell, 1996: p. 72; Waldron, 2001).

This morally normative approach to the separation of law and morality is associated with a complex political philosophy that points to the function of authoritative rules in human society (Raz, 1979; Shapiro, 2011). Social cooperation and coordination, dispute resolution, planning, and maintenance of public order, it is alleged, require rules and processes that are followed and enforced according to an authorized formulation that leaves as little room as possible for doubt and controversy as to their content and practical implications. These analyses often relate to the utility of rules as social devices that give effect to conventions that make it possible for individuals and groups to anticipate each other's conduct with considerable reliance in complex social circumstances. The utility of these rules and associated norms is relatively independent of their precise content since what matters is that there is some generally recognized and readily understandable convention, even if its clear content is morally controversial (Postema, 1982).

While these considerations explain why it may be socially important for some laws to be clear and applicable without controversy as to their meaning, the moral usefulness of other laws, such as those forbidding clearly harmful conduct, is more dependent on a common understanding and its moral acceptability on the part of those to whom it is addressed. Even here, however, there is a role for official determination as to what conduct is punishable and what is merely open to social criticism. This is because there can be controversy as to the precise nature of the harm in question. The need for definitive rulings derives from the existence of moral disagreement, for in fact there is rarely any one coherent system of positive morality, particularly where a culture encourages critical approaches and individuals have some autonomy in making up their own minds as to what they believe ought to be punished or recompensed. The political need to reach a working agreement on matters with the potential to generate conflict and disorder gives a morally significant role for the positivist idea of law as a system of mandatory rules whose authority depends on their adoption as law and not on their specific content.

Other moral arguments in favor of such a formalist conception of law are presented by Lon Fuller (Fuller, 1964), who demonstrates the connection between what he calls the governance of rules – rules that are clear, promulgated, prospective, practicable, and stable – and a society in which there is respect for autonomous moral agents who can reasonably be held responsible for their actions and accept that their obligations are part of a mutually beneficial political system. Fuller calls his theory a procedural form of natural law. Its formal requirements of 'good' law are part of a morality of mutual respect. He goes further than this and argues that a government that abides by the requirements of formally good procedural law will thereby tend to produce good substantive law. In a classic exchange with Fuller, H.L.A. Hart pointed out that Fuller's procedural natural law is 'compatible with great iniquity' (Hart, 1957). However, the general thesis that there are moral reasons for government in accordance with rules has clear affinities with prescriptive legal positivism, and it can be argued that Hart himself includes elements of this prescriptive approach (in a largely descriptive analysis) when he describes the benefits that arise for social order when the informal 'law' of simple societies is supplemented by 'secondary rules' that enable official determinations about what the primary rules of a society are and who has the right to interpret and change them (Hart, 1961: pp. 77–96).

Enforcing Morality

Analyses of the relationship between law and morality are often framed in terms of whether or not law should enforce morality, usually the dominant positive morality of a society. It is generally accepted that there is a sense in which morality cannot be enforced because truly moral conduct involves the willing acceptance of moral obligations. Thus, Immanuel Kant defined moral goodness as doing what is morally right because it is morally right and not, for instance, because the law requires it of us.

Further, it is rarely argued, as a matter of critical morality, that the law should require conformity to all and only conduct that is morally correct. Natural law theory tends to identify justice and the common good as that part of morality that is binding on human beings in a way that makes it appropriately enforced through positive law. The theory also requires governments to fill out positive law with lots of morally neutral ways that are required to give specific application to other natural law values. Classical legal positivists apply the general principle of utility to all moral questions, but point out that choosing a law is not making the same moral choice as choosing how to behave as an individual. Law involves sanctions and restricts liberty of action, which human beings enjoy and use to achieve their own happiness. Therefore, there are always moral reasons against enacting a law. This approach was developed by John Stuart Mill (1910) into the famous harm

principle according to which only harm-producing conduct may be prohibited, and then only when the negative effects of enforcing conduct are outweighed by the positive effects in reducing harm. He confined this harm to that which is caused to others, an antipaternalist positions that is a dominant strand in all liberal political philosophies.

The highly individualistic approach encouraged by the utilitarian moral theory is countered by various forms of communitarian analyses of society, including natural law theory. This conflict is well illustrated in a classic debate between Lord Devlin (1965) and H.L.A. Hart (1963) on the matter of decriminalizing homosexual conduct between consenting adults. Devlin argues that the basic institutions of a society, such as marriage, have to be protected in the interests of that society as a whole; therefore, it is treasonable to allow forms of conduct that undermine such foundational social institutions, and it follows that society has a right to enforce particular types of sexual organization. This was a response to Hart, who takes the view that sexual conduct of this sort is a purely private matter so that any disgust that the majority might feel toward such conduct has no bearing on the moral question of whether or not homosexual conduct should be a criminal offense.

Debates of this sort may be approached in a number of ways. Sociologically, Devlin's communitarian point can be investigated to see whether it is the case that the preservation of monogamous heterosexual marriage, as the dominant social institution with respect to sex and reproduction, does require prohibition of incompatible forms of sexual conduct. Other arguments center on the concept of toleration, the idea that it is morally desirable to allow people to follow out their chosen way of life even when you think that they are wrong to behave in this way. The arguments for toleration are complex (Mendus, 1988). For some people, toleration is an acknowledgment of the significance of moral goodness. For others, it is simply morally right not to interfere with the conduct of others when such conduct does not harm our interests. For others, it is a response to moral disagreement and the difficulty of reaching an objective decision about which competing form of life is morally superior. A more extreme form of this position is that choices between competing ways of life cannot themselves be moral choices, since all moral choices have to assume values that arise from a particular set of cultural circumstances. All these approaches either permit or encourage a pluralism of positive moralities that make it impossible for the law to enforce morality without a choice being made as to whose morality or which morality is to be enforced.

Responses to the problem of choosing which morality to enforce can be broken down into three categories:

1. Those that aspire to a morally neutral principle as a guide to which part of morality to translate into law. Mill's principle that only acts that cause harm to others may be criminalized has been presented in this light, but it is clearly part of the utilitarian position that causing pain to another is an immoral act, which is not a morally neutral position, especially when it excludes other possible grounds for moral disapproval.
2. Those that distinguish between private and public spheres, arguing that the morality that pertains to law is public morality, that is, morality about political and state relationships, while private has to do with the individual and her freely chosen associates. This shifts the argument to what is public and what is private, a principal battlefield being the sphere of family relationships. Feminists have powerfully pointed out that to classify the family as private is to leave this male-dominant sphere unregulated. Ultimately, 'private' comes to mean simply those matters that the law ought not to deal with, making it uselessly circular as a principle for determining the proper sphere of the law.
3. Those that seek to identify a certain number of basic rights that, while not morally neutral, allow for an extensive range of different forms of life to flourish as each individual and group pursues its own conception of what is good. This is the position developed by John Rawls in *A Theory of Justice* (1971) and enunciated by Ronald Dworkin in a series of works that represent the most sustained recent attempts to identify a morality that the law ought to enforce (1977, 1985). Dworkin's position is that judges should, within the confines of established legal decisions, exercise their own moral judgment in determining a point of law; this is a qualified form of natural law that requires judges to invalidate positive laws that are incompatible with natural law in the form of fundamental rights, which makes it a necessary condition of legality that a mandatory rule does not violate a human right, but still leaving considerable scope for laws whose content is determined solely by elected legislatures, often on the grounds that the right to self-determination is itself a human right (Waldron, 2006).

This third position arises from the emergence of the idea that there are human rights, a form of morally important universal rights, which establish legal limits to the powers of governments on the basis of certain fundamental moral requirements. Accepting that there are such moral limits and the desirability of enforcing them legally does not, however, enable us to achieve actual agreement as to what these rights require in practice. There is therefore a moral question as to who determines the specific content and the relative priority of the rights that are to be legally enforced. This takes us to constitutional questions that are crucial to contemporary arguments about law and morality.

If we believe that there is a moral method that enables us to identify human rights in an objective manner, then it is reasonable to enact by plebiscite or legislative process a general bill of rights that is then filled out and applied by courts in their determination as to whether the law produced by elected assemblies does or does not violate these rights. This may be regarded as a qualified natural law position since it assumes an identifiable lawlike morality particularly related to fundamental justice. It therefore makes sense to have rules of recognition that list these rights and leave it to the critical morality of the judiciaries to give them concrete application.

If we are skeptical about our capacity to solve disagreements about fundamental rights in this way and give high priority to the right of self-determination, then we can draw on a prescriptive form of hard legal positivism and suggest that it is for elected assemblies and popular plebiscites to determine the content of all law in light of the critical moral judgments of the people as a whole, and the duty of the courts to apply such laws

without reference to their own moral views, in which case the morality that is in the law is determined independently of and externally to the process of law application.

This might require legislatures to turn to the values that they believe give the best moral interpretation to the human rights identified for implementation through formally good positive rules that can be applied without further moral adjudication to concrete social circumstances. A natural law alternative posits that it is humanly possible to reach morally correct answers to such disputed matters and that judiciaries are in the best position to discover the correct moral strength and scope to give to the human rights whose interpretation is entrusted to them. Legal positivists regard this as a confusion of morality and law, but this need not be the case if the aim is the division of legislative power between legislatures and courts rather than a strict institutional separation of legislative and adjudicative powers. The choice between these two perspectives is one of the most important contemporary moral choices regarding the best way of conceptualizing and institutionalizing distinctions between morality and law.

Abstract

This article discusses how the intersection of perennial legal questions and new neuroscientific advances has fueled the emergence of a new field: law and neuroscience. It provides an overview of issues, discussing both the promise and the limitations.

Introduction

In barely a decade, a new field of law and neuroscience (sometimes called 'neurolaw') has emerged. Its quick growth is evident not only from the increasing frequency with which attorneys offer to introduce neuroscientific evidence in court, but also from the sharp rise in conceptual and empirical scholarship, the proliferation of neurolaw conferences, the founding of multiple international neurolaw societies, the increase in neurolaw course offerings (in law schools and beyond), the creation of joint degree programs, and the investments by public and private entities that have fueled interdisciplinary collaborations and research (Jones et al., 2013a,b).

As with any new field, there is wheat and chaff; a considerable proportion of the early efforts has involved developing ways to identify, evaluate, and separate the two. Given the technical nature of neuroscientific capabilities, a legal system needs guidance on how to chart a course that maximizes the promise of neuroscientific insights and minimizes the potential perils of incorporating them. Some of the best work in law and neuroscience to date (e.g., Morse and Roskies, 2013) partners experts from both fields to move forward in a cautious but deliberate – instead of purely reactive – way (Jones, 2013a).

Three cases, from three different countries, illustrate some of the many contexts in which neuroscientific evidence has – for better or for worse – influenced legal proceedings. In 2008, prosecutors in India secured the conviction of a woman for the murder of her fiancé (*Maharashtra v. Sharma*, 2008). The prosecution presented key evidence – data collected from the defendant's brain – that supposedly corroborated her suspected involvement in the murder. In 2009, an Italian court reduced the sentence of a woman convicted of murdering her sister (and attempting to murder her parents) from life in prison to 20 years in prison. The court cited, as relevant to this reduction, structural brain abnormalities as well as low levels of an enzyme responsible for maintaining proper levels of various neurotransmitters in the brain, a combination that is thought to increase violent tendencies (Feresin, 2011). In 2012, the United States Supreme Court concluded that it was unconstitutional for juvenile offenders to be sentenced to mandatory life in prison without the possibility of parole (*Miller v. Alabama*, 2012). In explaining its decision, the Court cited (alongside other lines of evidence) neuroscientific findings regarding the differences between adolescent and adult brains.

Cases, such as these, and the growth of scholarship and public interest that surround neurolaw issues generally, suggest that neuroscience will (again for better or for worse) ultimately play an increasing role in legal proceedings. What accounts for this? It likely results from the combination of two distinct factors that have rapidly converged over the past decade or so.

First, the legal system has long struggled to answer important questions – questions about what goes on in people's heads, and why – that society demands be answered. For example: Was the defendant responsible? What did the defendant intend? How competent is the individual to stand trial? Is this witness lying? What capacity did the defendant have to act differently? And will the person be a repeat offender? Correctly answering each of these questions is essential to the just enforcement of the law. Yet to various degrees answering them requires legal decision makers to act as amateur mind readers – of questionable accuracy.

Second, robust advancements in cognitive neuroscience, driven in large part by technological developments related to brain imaging, appear to offer some promise in helping to answer these perennial questions (Posner and Raichle, 1994). Perhaps, the thinking goes, structural or functional brain measures can aid judgments about whether someone is lying, responsible, and likely to recidivate. Perhaps, some hope, technology can increase the accuracy of our conclusions by providing objective, clear, and quantifiable data.

What neuroscience can and cannot provide to the legal system is, of course, a matter of debate across multiple fora (Wagner, 2010; Weisberg et al., 2008; Morse, 2011; Greene and Cohen, 2004; Morse and Roskies, 2013, Freeman and Goodenough, 2009; Jones et al., 2014; Greely and Illes, 2007). Which is as it should be – because the potential for misunderstanding or misuse is (as with any technological or scientific advancements) concerning and real. The purpose of this article is therefore to introduce some of the potential promise of neurolaw, as well as to raise some cautions and limitations, lest hopes outpace capabilities.

Technological Capacities

Although it is by no means the only neuroscientific technique of importance, functional magnetic resonance imaging (fMRI) – which provides unparalleled ability to link brain function with brain structure – is attracting increasing attention in legal arenas. Introduced in the early 1990s, fMRI takes advantage of

physical properties of oxygenated and deoxygenated blood to measure changes in blood flow to brain regions. This change in blood flow is linked to changes in neural activity. By analyzing the change in blood flow across the brain and across the experiment, neuroscientists can create compelling evidence linking perception and behavior to neural activity in specific regions of the brain (Friston et al., 1998). This has allowed investigators to create cognitive models that are of interest to the law, such as the brain systems that support social decision making, deception, and cognitive capacity (Rilling and Sanfey, 2011; Kozel et al., 2005; Bunge et al., 2002; MacDonald, 2000).

In addition to linking neural activity in a brain region to cognitive and perceptual processes, advancements in fMRI have provided investigators with the ability to study the functional connectivity between brain regions and to decode patterns in neural activity that can detect, describe, and predict perception and cognition in human subjects. For example, brain connectivity studies have been used to reveal the limited influence of top-down cognitive control systems in adolescents (Luna et al., 2010) and pattern analysis studies have revealed patterns of brain activity that can reliably indicate that subjects recollect stimuli presented to them (Johnson et al., 2009).

fMRI is not the only technology used for legally relevant neuroscience research. Positron emission tomography (PET), diffusion tensor imaging (DTI), electroencephalography (EEG), and repetitive transcranial magnetic stimulation (rTMS) have all been used to inform legal decisions or questions in a variety of litigation or research contexts. Each of these technologies provides the investigator with unique sets of tools (the details of which are beyond the scope of this article) that can observe or manipulate the human brain.

Caveats and Cautions of Brain Imaging

However remarkable, neuroscientific technologies and methods – like all techniques and methods – have their limitations. And, given the stakes involved, it is particularly important that legal systems have informed and clear-eyed understandings of those limitations. Here we divide the major concerns regarding functional imaging evidence into two categories: those involving mistaken facts and those involving mistaken inferences.

In the realm of mistaken facts, it is easy to misunderstand what brain images actually represent (Jones et al., 2009). For example, fMRI brain images, which appear to show brain regions as 'lit up,' are not in fact the brain scanner's output of where neural activity is located. Indeed, fMRI provides no direct measure of neural activity at all. Instead, the different colors on an image indicate different results of statistical analyses performed on minute changes in blood flow in a set of brain regions, across many trials of an experiment (and, usually, across many subjects). On one hand, there are many reasons to believe that increased blood flow to neurons is strongly associated with increased neural activity. Changes within brain tissue in the demand for blood are thought to be a reliable proxy for changes in the activity of neurons within the brain. On the other hand, the exact relationship of blood flow and neural activity is poorly understood.

The most prevalent of mistaken inferences about fMRI reflects the assumption that if a region shows activation with a particular task or behavior then that region is therefore causing that particular task or behavior. Yet, as in other contexts, correlation is not causation. In fact, fMRI is mainly a technique of discovering correlations, which must still be further investigated before claims of causality can be made legitimately (Logothetis, 2008).

Another important example of mistaken inference follows from overlooking the crucial distinction between group and individual data. Most brain research is concerned not with what is true about any given individual, but with what is true about the average individual within the studied group. Group averaged data do not necessarily provide an accurate description of what is occurring in each individual. To the extent that law is often engaged in adjudicating the futures of individuals before the court, one must exercise great care and caution when trying to reason one's way to an individual's brain from a general finding grounded in the brain data of groups (Faigman et al., 2014). For example, if a group-level study demonstrated that those telling lies have increased activity in a particular brain region, we could not say with confidence that any given individual will also demonstrate increased activity in that same region when telling a lie.

The combination of mistakes of fact and mistakes of inference yields a quite reasonable concern that jurors and others in the legal system may afford more weight to neuroscientific evidence – particularly vivid, colorized images – than the underlying science warrants. Some early studies seemed to indicate that jurors were likely to be prejudiced by such evidence (Gurley and Marcus, 2008; Weisberg et al., 2008). Later studies have painted a more complicated picture, in which jurors are generally more discerning than originally thought (Saks et al., 2014), though they are still likely, in some contexts, to give undue weight to brain images (Saks et al., 2014; Schweitzer et al., 2011).

The main takeaway is that in neuroscientific evidence the law encounters a highly technical domain, the chief products of which – however vivid – must first be contextualized within a series of interrelated caveats and cautions, and then be evaluated – on a case-by-case basis – within the specific legal context in which the science may, or may not, directly aid the decisions at hand.

Ways in Which Neuroscience May Aid Law

The 'law,' of course, is not one thing; it is rather a vast web of institutions and rules. The bulk of these are specific to defined jurisdictions in which they operate. In the United States, for example, most criminal law is a matter of state rather than federal jurisdiction. And the state laws can vary (and often do vary) as much as do the states themselves.

Because of this, it is difficult to speak generally about the role and influence of neuroscience in the law. Nonetheless, one of us has proposed that there are seven main (and sometimes overlapping) ways that neuroscience can aid law (Jones, 2013b):

1. *Buttressing* – by increasing juror confidence in a conclusion to which other, nonneuroscientific evidence already

independently points (such as in the context of 'diminished capacity' determinations);
2. *Challenging* – by calling into question or contradicting either other evidence in a case or a relevant legal assumption (such as those reflected in certain evidentiary rules);
3. *Detecting* – by identifying the existence of legally relevant facts (such as injuries, lies, or pain);
4. *Sorting* – by separating people into useful categories (such as those most likely to respond to drug rehabilitation);
5. *Intervening* – by providing new methods to achieve legal goals (such as through pharmacological interventions that would help to reduce recidivism);
6. *Explaining* – by illuminating decision pathways with information that may lead to more informed and less biased decisions (such as in the context of third-party punishment decisions); and
7. *Predicting* – by improving law's ability to estimate probabilities of future behavior (such as future violence).

For purposes here, however, a rough and different cut into two main functions of neuroscience in legal arenas will serve. Consequently, the Section Neurolaw and Individuals considers ways in which neuroscience can help to discover facts that are legally relevant (such as: How injured is this person's brain?). The Section Neurolaw and Groups considers ways in which neuroscience can inform broader policy making (such as: To what extent are adolescents similar to or different from adults?).

Neurolaw and Individuals

Legal systems – in their courts, for instance – are often engaged in making decisions about the rights, transgressions, and lives of individuals. Often the content and nature of those decisions depend intimately on which version of hotly contested facts is the more accurate one.

Multiple sources of evidence may bear on the process of deciding what – at least for the purposes of law – those facts really are. For example, when a key legal issue is whether a defendant is legally insane, a court may hear and weigh conflicting evidence from clinical psychologists, psychiatrists, employers, neighbors, and the like.

Although the behavioral evidence is of course crucial in such contexts, neuroscientific evidence (of considerable brain tissue degradation, for example) could help the legal system choose which version of contested facts is most likely. This section illustrates a number of contexts in which the main value to law of neuroscientific evidence is in helping it to determine the facts, frequently in the context of litigation.

Brain Injury and Pain

The intersection of neuroscience and law arguably originated with the use of neuroscience to better define and detect brain injury. This occurred primarily in the realm of personal injury (or 'tort') law, which is a type of civil action. A successful personal injury claim must typically demonstrate: (1) actual injury; and (2) a causal link between the defendant's actions and the claimant's injuries.

Due to the dearth of knowledge about brain function, proving a causal link between the defendant and the injury, or even demonstrating an actual injury, was impossible for many actual and potential claimants. As an example, imagine two different car accidents caused by equally negligent actors. One accident results in broken legs, but no trauma to the head, while the other results in massive trauma to the brain, without breaking any bones. Despite the likelihood that the latter will be lifelong and life changing, it is significantly more difficult to establish the injury, link it to the act, and obtain a judgment that is commensurate with the injury (Zitter, 1997; Luce, 2012).

Because neuroscience provides the tools and techniques to detect and classify brain injury and estimate a prognosis, it has been increasingly called upon to inform legal claims involving brain injuries. Advances in neuroscience currently appear to provide better specificity and sensitivity when diagnosing and assessing these injuries (Lewine et al., 2007).

This is important because traumatic brain injuries (TBI) are quite common. The Centers for Disease Control estimates that TBI contributes to one third of all injury-related deaths in the United States and that, in that country alone, 1.7 million people sustain a TBI each year, 52 000 of whom die shortly thereafter. And lawsuits involving TBI have become increasingly prominent. For example, many former players of American-style football have sued over brain injuries allegedly sustained across their careers. Corroborating evidence for the causes of the cognitive and affective impairments they allege, which is hard to demonstrate while still alive, has come from investigation of the brains of deceased players, which often exhibit chronic traumatic encephalopathy (CTE) (McKee et al., 2009).

In addition to providing for the improved detection and classification of brain injury, neuroscience also provides evidence that could potentially alter how we define brain injury in the first place. In large part, the law recognizes pain as an injury. However, the subjective nature of pain has influenced how the law treats pain. New neuroscientific evidence may come to challenge this in at least two ways.

In the first instance, legal systems have struggled with the fact that pain is a subjective experience, difficult to prove, and possible to fake (Pryor, 1991). A common way to circumvent this problem is to require indicia – such as trauma or disease – beyond the subjective reporting of pain. This approach is only satisfactory, however, when such objective indicia are available and consistent with the magnitude of subjective pain. In cases of chronic pain, such as fibromyalgia, it is very difficult for those suffering to establish that they have the subjective experience of chronic pain. And, even though 10% of the population suffers from different forms of chronic pain, those who bring claims related to their chronic pain are frequently thought to be malingerers or outright fakers. Brain imagers are attempting to develop methods to more reliably observe the subjective experience of pain (Rainville et al., 1997). As these methods improve, they may help to identify pain when it is present and to raise doubts when it is not.

In the second instance, brain imaging data are undermining the law's long-standing divide between physical and psychological pain. Jurisdictions vary, but it is generally the case that remedies for psychological pain are not available without demonstrating a physical harm. This rule likely arose to serve

an evidentiary purpose. But neuroscience is calling into question one of the basic premises behind the rule. Specifically, recent neuroimaging results reveal that psychological pain engages the same brain regions as physical pain (Eisenberger, 2012). In addition, to the extent that certain brain disorders (such as posttraumatic stress disorder (PTSD) and other anxiety disorders) are classified as psychological, brain imaging research may demonstrate the physical basis for the disorders (Shen, 2013). This can frame a discussion wherein psychological and physical traumas are potentially seen as one and the same.

Cognitive Capacity and Intent

In most legal systems, criminal responsibility requires both a bad act and a culpable state of mind. Neither alone is sufficient. For example, a person judged to be insane is not ordinarily treated the same as a noninsane person who committed the identical act. The substance, procedures, and burdens of using insanity to escape criminal culpability vary widely across jurisdictions (Simon and Ahn-Redding, 2008). Despite the variability, there are three primary legal mechanisms by which neuroscience can influence questions regarding the culpability of a defendant who has committed a proscribed act.

One mechanism is for the defendant to claim that his condition satisfies his jurisdiction's insanity defense. Insanity defenses are created by courts or by legislatures and allow for defendants to argue that they are excused from full criminal responsibility on the basis of mental disease or defect. The type or extent of the disease or defect required for an insanity defense varies. A majority of US jurisdictions use the 'M'Naghten rule.' The rule, which originated in a nineteenth-century English case (and is named after the defendant in that case), requires a defendant to establish that he lacked the ability to understand the nature and quality of his actions. Because the conscious experience of understanding the appropriateness of one's own actions is a complex and poorly understood concept, neuroscience has been of limited use in operationalizing such a rule. However, as neuroscience begins to uncover the mechanisms supporting human consciousness, its contribution toward these deliberations may increase. A sizable minority of US jurisdictions and a number of other countries use a test focused on the question of the defendant's volitional control as opposed to his cognitive capacity (as is the case with the M'Naghten rule). The neurological disorder of frontal lobe dysfunction (FLD) is a useful example of the difference between these two rules.

Individuals with FLD suffer from severe deficiencies in impulse control and therefore cannot conform their behavior to the expectations of the law and society as easily as do non-FLD individuals (Brower and Price, 2001). Nonetheless, these individuals maintain the ability to understand the criminal nature of their actions because the area of cortex responsible for this cognitive capacity is seemingly preserved in cases of FLD. As a result, individuals with FLD do not ordinarily meet the requirements of legal insanity under the M'Naghten rule but – because their ability to conform their behavior is deficient – they may be successful in making a claim of insanity in those jurisdictions that use volitional tests. Even then, however, neuroscience may ultimately be of limited use, because it has yet to provide a neurobiological model of volition that is consistent with its legal understanding. In other words, volition as the law understands and defines it does not map comfortably onto an identical concept in neuroscience. This explains both the criticism surrounding the use of neuroscience to establish legal insanity and the limited impact of neuroscience on the success of such claims.

Despite the limited influence of neuroscience in assisting claims of legal insanity, neuroscience continues to be used to challenge criminal responsibility by challenging the prosecution's prima facie case. Generally, to establish its prima facie case, the prosecution must establish a level of culpable intent accompanying the acts, often referred to as *mens rea*. While the gradations of *mens rea* vary across jurisdictions, the most severe criminal statutes generally demand that the defendant acted with either general or specific intent with regards to the resulting harm. With increasing frequency defendants will argue that brain abnormalities, visualized through brain imaging, provide evidence that the defendant was incapable of formulating the required intent and therefore should be found not guilty of the charges (Edersheim et al., 2012).

Finally, as of now defense attorneys have found the use of neuroscience to be most useful at the sentencing phase of a trial. In many jurisdictions and for many crimes, trials will take place in two parts. In the first part fact finders evaluate whether the defendant is guilty of the charges brought against him. In the second part, if the defendant is found guilty, a judge or a jury will determine the appropriate sentence. For a variety of evidentiary reasons, the bar for admissibility of evidence is set much lower for this latter stage. Taking advantage of this, some attorneys have started to introduce neuroscientific evidence in an attempt to argue that the defendant should be given a more lenient sentence. While empirical studies have yet to demonstrate a significant effect of the use of neuroscience at this stage of the trial, anecdotal evidence indicates that it has already influenced sentencing in some cases (Jones and Shen, 2012).

Lie Detection and Recognition

Prospects for brain-based lie detection have received great attention – both because the idea of reliably detecting lies is inherently alluring and because criminal defense lawyers have, on at least several (so far unsuccessful) occasions, tried to introduce fMRI-based lie detection evidence into trials. Prior to the use of brain scans to uncover deception, the most recent efforts to introduce physiological measures as evidence of truth or deception have involved the so-called 'polygraph' – which measures peripheral indicators of cognitive states such as blood pressure, heart rate, and skin conductivity. The reliability of these measures as indicators of lies is a source of much debate. Although the polygraph is still used widely in interviews and interrogations, US courts routinely exclude polygraph evidence (in light of, among other things, a 2003 report of the United States National Academy of Sciences, which labeled it unreliable and biased).

fMRI techniques for identifying lies seek to bypass indirect physiological indicators, which can be skewed by countermeasures or nonindicative anxiety, and find direct neural signatures of the cognitive processes involved in deception. Proponents argue that this would reduce the risk of both false

positives and false negatives. Although some data suggest that these assessments can have accuracy rates approximating 90%, other data suggest a far lower accuracy, approaching or no better than chance. Beyond this, several robust critiques note problems with ecological validity, the 'real-worldness' of the studies (e.g., Farah et al., 2014). For example, almost all studies to date involve individuals from limited demographics practicing relatively low-stakes deception without engaging countermeasures. Moreover, they are almost exclusively limited to 'instructed lie' experimental designs, in which subjects are explicitly told to try to deceive the researchers.

The extent to which instructed lies are meaningfully like 'real' lies, or like real lies under high stakes (such as the risk of imprisonment, for instance) is questionable. One respected neuroscientist, Anthony Wagner, has studied all published studies of fMRI-based lie detection and has concluded that, at the present time, the literature does not provide an accurate indicator of the sensitivity or specificity of fMRI-based lie detection (Wagner, 2010). The few courts to consider the matter have agreed with this assessment, and have ruled such evidence inadmissible, though it may become admissible in the future if methodological short-comings can be overcome (*U.S. v. Semrau*, 2010; *Wilson v. Corestaff Services*, 2010).

An area of active research closely related to deception concerns use of fMRI (or EEG) to detect actual autobiographical recognition of various stimuli, such as pictures of scenes or people, names, and the like. Early work in the field appears remarkably promising (Rissman et al., 2010). And although these techniques are also subject to various important limitations (such as vulnerability to countermeasures) the techniques have potential application in a number of legal contexts, should the limitations be overcome effectively.

Future Behavior: Assessing Dangerousness

Many jurisdictions across the globe depend on assessments of dangerousness when deciding sentence or considering the release of imprisoned criminals. Historically, these assessments have come in the form of expert reports (from clinical psychiatrists, for example). Actuarial assessments, however, are increasingly prevalent alternatives, widely thought to be more accurate (Grove et al., 2000).

Because risk of future dangerousness is, essentially, a question of the proclivities of the brain, many hope that neuroscience can and will improve the accuracy of these assessments. In this vein, one recent study compared 4-year recidivism rates of former prisoners who had been brain-scanned while in prison. It found that one neural assessment using fMRI provided a robust level of predictive power, even when controlling for other risk factors and psychological measures (Aharoni et al., 2013). Whether these assessments are viable in practical use, and the extent to which they enable individualized assessments, as distinct from group-averaged ones, remains to be seen.

Neurolaw and Groups

The prior section illustrated contexts in which neuroscience may provide information about individuals (such as a defendant) that can aid legal decision makers (such as courts) in making decisions relevant to those individuals alone. But there are also times, in contrast, when neuroscience may provide information about groups (such as adolescents, addicts, or eyewitnesses) that aid legal decision makers (such as legislators or courts) in making or refining broad policies. This section provides several examples.

Adolescent Justice

Children are everywhere recognized as not fully responsible for their behaviors. Adults are presumptively responsible. In between lie adolescents, for whom determining the appropriate level of responsibility has long vexed legal systems, as they balance a society's desire for individualized justice with both the difficulty of reliably assessing the relative maturity of individuals and the virtues of establishing easily administrable bright-line rules.

For nearly all the twentieth century, most western jurisdictions created specialized frameworks to process adolescent offenders. The primary characteristics of these regimes were an abundance of decision-maker discretion, a focus on rehabilitation and intervention, and very limited use of retributive punishment. The 1980s and 1990s, however, witnessed a global shift toward a less paternalistic and increasingly punitive justice system for adolescents (Junger-Tas and Decker, 2006). This shift is largely attributable to increasing crime rates, increasing fear within the population, and increasingly widespread beliefs that adolescents were morally responsible for their actions.

More recently, the retributive approach to juvenile justice has been losing favor with policy makers. That shift coincides with (and may or may not be partially attributable to) marked advances in understanding the adolescent brain. For example, a large body of neuroscientific evidence has clarified the ways in which the adolescent brain is categorically different from a fully developed brain. Structural analysis and fiber tract analysis have demonstrated that the human brain continues to develop and mature until around age 25. fMRI studies have revealed strong functional differences – between adolescent and adult brain systems – in delaying reward, impulse control, and emotional processing. Combining these findings with the behavioral findings, many neuroscientists conclude that adolescents do not have the full capacity for cognitive control over their behaviors and are not nearly as able as adults to modulate their socially and emotionally aroused inclinations with deliberative processes (Steinberg, 2008).

Of course, the legal implications of such evidence are a source of much debate. Some critics argue that the neuroscience is of little use, if not completely irrelevant, because it adds nothing to what we already knew from the social science research – not to mention lay observation of adolescents. We already knew, they note, that adolescents are irrational risk takers, susceptible to peer influence. Other critics question the utility of the information in deciding what to do with a specific adolescent – who might be much more or much less immature than average (Maroney, 2010; *Roper v. Simmons*, 2005 Scalia dissenting). In contrast, proponents of informing legal policy making with neuroscientific evidence

argue that it both deepens and makes more concrete and vivid our appreciation of precisely how different adolescents are, and why (Steinberg, 2012).

Despite the uncertainty surrounding the legal weight of such evidence, neuroscience has begun to be introduced as evidence in the youth-related policy decisions made by courts and legislatures. Of course, the causal role of neuroscience in these decisions is disputed.

For example, between 2005 and 2012 the United States Supreme Court issued three decisions detailing the protections that the Constitution affords adolescent offenders. In each case the Court was provided with group-based neuroscientific evidence (among much other evidence). And in each case the Court clarified or expanded the group-wide reach of those protections. The first opinion did not mention neuroscience (*Roper v. Simmons*, 2005), the second mentioned it in a footnote (*Graham v. Florida*, 2010), and the third referred to 'cutting-edge neuroscience' in the text (*Miller v. Alabama*, 2012). It is unknown whether the reference had an actual effect on the outcome, or instead was a citation of convenience.

Separately, a State Senator from Washington reports that neuroscientific evidence about the development of the human brain is what finally convinced her colleagues to pass bills related to childhood education, after 7 years of considering and rejecting similar bills unaccompanied by neuroscientific evidence. While we cannot truly know the impact of neuroscience on any given legislator, the State Senator reported that those who had been most ardently opposed to spending money on childhood education bills came up to her and said that the neuroscience helped them 'get it' (Gehrman, 2007).

Whether in fact the neuroscience had a causal role, these two examples illustrate ways in which group-level neuroscientific evidence appears to be affecting some discussions at the broad policy-making level.

The Limits of Human Judgment and Memory

Neuroscience can also be relevant, at the broad group level, when helping us understand – so as better to develop policies to combat – various frailties that can impede the fair and efficient provision of justice. Two examples suffice to make the point.

First, how might we better understand and combat bias in legal decision makers? The initial step is to better understand the mechanisms by which key legal decisions – such as those by jurors determining guilt, and by judges determining a sentence – are made. Neuroscience has already begun discovering the brain bases of these processes (Buckholtz et al., 2008; Buckholtz and Marois, 2012). A next step is to deploy neuroscientific techniques to deepen our ability to understand and perhaps to combat the influences on and origins of prejudice and bias. Neuroscience has already moved in this direction, helping to uncover what is happening, neurally, during behaviors that reflect unconscious bias (De Martino, 2006; Stanley et al., 2008). Indeed some recent studies have found that brain imaging can be superior to psychological measures at uncovering implicit biases (Korn et al., 2012). Of course, scanning the brains of jurors and judges prior to trials will probably remain an unworkable (or undesirable) proposition, but by revealing and understanding the neural nature of bias, and our susceptibility to it, neuroscience may begin to address what has long been seen as an intractable issue in our criminal justice system.

Second, consider the limitations of eyewitness testimony. Eyewitness testimony is both gravely important and frequently incorrect. For example, of the first 250 prisoners cleared off death row by DNA evidence in the United States, eyewitness testimony was a factor in more than 75% of the convictions. This presents a unique peril to justice because, in the realm of eyewitness testimony, the true threat may come not from those who purposefully undermine the truth, but instead from those who firmly believe that their false memories are true.

Neuroscience has helped to demonstrate that – contrary to assumption – humans are not neurologically capable of maintaining memories of events in a manner similar to a tape recorder that can be played back for the benefit of the court (Schacter and Loftus, 2013). Neuroscience studies have also demonstrated, promisingly, that it is in some contexts possible to differentiate between true and false memories, using brain data, even when the subject does not know the difference (Slotnick and Schacter, 2004). Moreover, neuroscience has helped to reveal that the act of retrieving a memory (as in the course of an investigation, for example) creates a susceptible version of the memory that can be distorted (Nader and Einarsson, 2010). Learning more about how memories can be stored, retrieved, and modified has the potential to affect not only the legal system's policies about how memories (and the jury instructions regarding them) are handled in the courtroom; it may also aid efforts to constructively reform the process of collecting and documenting eyewitness testimony in the course of an investigation.

Conclusion: The Future of Law and Neuroscience

There is no denying that recent and rapid advances in cognitive neuroscience are fueling extraordinary discoveries about the operating machinery of human experience, perception, decision making, and behavior. Brain imaging technology in particular is enabling previously unimaginable capabilities: to noninvasively observe the structure and function of a healthy human brain, both at rest and on task.

What these new capabilities will ultimately reveal about our brains, and about us, remains unclear. Equally unclear, but crucially important, is how legal systems across the world will engage these new capabilities in a manner that improves the system's ability to make high-stakes decisions, about real people, under conditions of marked uncertainty.

Fortunately, there are many efforts underway – individual and collective, public and private, national and international – to help and to guide this engagement. In the end, legal systems must evaluate neuroscientific evidence in an informed, robust, and skeptical but open-minded way – in order to navigate successfully between both the promise and the peril of incorporating neuroscientific insights into legally relevant decision making.

Abstract

This article describes the progressive development of disability law, particularly in light of international developments that are transforming domestic disability law frameworks. It provides an overview of the conceptualization of disability in law, charting the shift from a medical model to a social model of disability and more recently to a human rights model. The abstract covers the implications of the Convention on the Rights of Persons with Disabilities (CRPD), and the processes and approaches for translating international disability law standards into national level law. It sheds light on the contemporary disability rights landscape in the light of dramatic legislative action promoted by the adoption of the CRPD.

Introduction

People with disabilities represent 15% of the world's population, many of whom experience discrimination and exclusion and live in poverty, with restricted access to basic goods and services (World Health Organization and World Bank, 2011). The United Nations adopted the Convention on the Rights of Persons with Disabilities (the Convention or CRPD) and its Optional Protocol in 2006, with the aim of establishing a comprehensive framework to promote and protect the rights of persons with disabilities (CRPD, 2006; Optional Protocol, 2006). The Convention elaborates minimum legal standards to address disability discrimination and to promote equality for persons with disabilities in all spheres of life – political, social, economic, cultural, and civil (Schur et al., 2013). The Optional Protocol allows individuals and groups to seek redress at the international level when these standards are not met, and provides for an independent committee of experts to undertake investigations into serious breaches of disability rights as set forth in the Convention.

At the time the Convention was proposed, in 2001, very few countries around the world had any disability law or policy framework. Its drafters recognized that, throughout the world, national disability law and policy remained underdeveloped or, worse, contained explicitly discriminatory provisions that strip persons with disabilities of their rights (Stein and Lord, 2012). In many respects, law was a tool for exclusion and oppression of persons with disabilities. Fewer than 50 countries had disability discrimination laws, while many countries limited the rights of persons with disabilities through laws and policies, that for instance, excluded persons with disabilities from exercising their right to vote, placed arbitrary restrictions on their right to certain types of employment or limited their ability to take part in the judicial process as witnesses, jurors, or even claimants. In other examples, disability was addressed narrowly, as a social welfare matter, typically coordinated at the government level by ministries of health or social welfare (Degener and Quinn, 2002).

Since 2006, many countries have adopted the standards in the Convention through the process of ratification (UN Enable). As of 26 August 2013, 133 countries have ratified and 156 have signed the Convention (UN Enable). Ratification is an important step in recognizing disability rights at the national level. Countries around the world are undertaking comprehensive and cross-cutting reviews to assess the compatibility of their laws to the Convention and, where needed, to reform and develop laws to bring the national legal system into alignment with the Convention's standards. Law reform is one step in ensuring full respect for the enjoyment of the rights of persons with disabilities; yet other measures are needed in order to effect real change. Budgets must be allocated to ensure adequate implementation of laws; the public must be made aware of the rights of persons with disabilities to ensure that their actions do not obstruct persons with disabilities from enjoying their rights; and monitoring mechanisms must be put into place to protect disability rights (Lord and Stein, 2008). In addition, persons with disabilities and their representative advocacy organizations must have the capacity to claim their rights and to participate in law, policy, and programming (Lord et al., 2012).

This article considers the progressive development of disability law, particularly in the light of developments at the international level that have promoted the transformation of domestic disability law frameworks. It first provides an overview of the conceptualization of disability in law, focusing on transitional perspectives and examining current trends. It charts the shift from a medical model of disability to a rights-oriented social model of disability in law and policy. Thereafter, the article considers the CRPD framework and its implications for law reform. Then, it addresses the processes and approaches for translating international disability law standards into national level law. The article concludes with observations on the contemporary disability rights landscape in the light of dramatic legislative action promoted by the adoption of the CRPD.

Conceptualizing Disability in Law

The conceptualization of disability in law and policy has progressed, in the post–World War II era, from a limited, medicalized, and welfare-oriented understanding to a rights-based, sociocontextual perspective. The implications of these perspectives are significant and help to explain the gradual

enlargement of the disability law landscape. The various models of disability are discussed in turn.

Models of Disability and Their Influence on Disability Law

As stated by Kimberlé Williams Crenshaw, "law … embodies and reinforces ideological assumptions about human relations that people accept as natural or even immutable" (cited in Berg, 1999: p. 4). The conceptualization of and cultural discourse on disability in society has evolved overtime, and these changes are reflected in the nature and scope of laws that impact persons with disabilities.

The early understanding of disability centered on its perceived biological origins, wherein impairment resulted from an injury, disease, or other medical condition (Logue and Blanck, 2010). This 'medical model' of disability focused on the impairment as a deviation from or disfigurement of the 'normal' human body, and conceived of a person to be less capable than his or her peers without disabilities. The medicalization of disability is derived from assumptions and expectations of persons without disabilities about those experiencing life with a disability. This resulted in the notions of the disabled being weaker, less able to undertake and effectively accomplish activities such as going to school and getting a job, and more dependent on others for their subsistence (Berg, 1999; Blanck, 2004; Ingram, 2006; Muller, 2011; Stein, 2007).

With the cultural discourse focused on the presumed deficiencies of persons with disabilities and their resulting economic needs, the medical model shaped disability welfare laws around the world. Social welfare laws for persons with disabilities often equate disability with the inability to work and earn an income, and create government benefits that support people economically as well as provide them access to necessary medical, rehabilitation, and support services, for example, through medical insurance, cash benefits, and personal assistance services (Bagenstos, 2004; Blanck et al., 2013; Jones and Marks, 2001). While social welfare laws for persons with disabilities were established early on in the twentieth century, they continue to provide government benefits and assistance in most countries despite the newer rights-based legislations.

Beginning in the 1970s, disability advocates began to question and dismantle the dominant medical view of disability, and raised a different reason for the exclusion of the disabled in society. They countered that disability was a social, rather than a medical, condition, caused by the challenges in interacting with environments and systems, which are not designed to accommodate human differences and are thus inaccessible to persons with disabilities (Gray et al., 2003). The 'social model' of disability challenged the presumption that benefits and welfare were the legal solutions to the exclusion of people with disabilities, and instead advocated for legislation that would remove barriers to their full social and economic participation. The social model of disability is seen as a 'minority model' of disability by some legal scholars, in that it defines persons with disabilities as a group, like other minorities, that has been willfully excluded from mainstream society due to stigma, negative attitudes, and stereotypes about their abilities and capacities (Bickenbach, 1999). The social model of disability shaped the next iteration of disability-related legislation with a focus on antidiscrimination and equal access (Blanck, 2014).

Antidiscrimination law aims to provide protections and safeguards to minority groups and promote equality of opportunity, along with resources to seek compensatory damages (Jones and Marks, 2001). As the social model of disability became the dominant view of disability, countries adopted antidiscrimination into their disability legislation either as the foundational premise or within sections targeted at employment and access to public and private goods and services. The Americans with Disabilities Act passed in 1990 has been widely viewed as the standard bearer of disability civil rights and antidiscrimination laws that were enacted in many countries in the 1990s (Blanck, 2006, 2008; Stein, 2007). In many countries, antidiscrimination law is coupled with legislation establishing quotas for persons with disabilities in education, employment, political representation, housing, and other domains (Byrnes, 2011; Degener, 2005; Kim, 2011) as a corrective measure to level the playing field. The social model of disability is related to the independent living movement in western societies where persons with disabilities fought for their right to live within inclusive communities independently, rather than be segregated in institutions or other exclusionary arrangements (Blanck, 2006).

The social model of disability focuses on the corrective measures required in a society to break down environmental and attitudinal barriers to participation, and has conceptually organized the fight for civil rights for persons with disabilities. However, with time scholars and advocates have proposed a more comprehensive approach that looks beyond civil rights and liberties and frames disability as a human rights imperative. Stein and Stein (2007) describe this approach as a way to go beyond seeking only first generation civil and political rights through antidiscrimination legislation, to seeking first and second generation rights that include equality of opportunity on the "full spectrum of social, cultural, and economic measures" (p. 1205). A comprehensive 'human rights model' of disability will advance laws that aim to recognize the human rights of persons with disabilities; that is, "the fundamental, universal and indivisible principles by which every single human being can gain justice and equality" (Albert and Hurst, 2006: p. 2). The human rights model of disability has been the founding element behind the CRPD, the first international treaty on disability. The next section discusses the application of human rights standards to disability law.

As described above, different conceptualizations and cultural realities often lead to different legal responses to disability. Despite their differences, these legal responses frequently coexist within legal systems; countries use a combination of welfare, antidiscrimination, affirmative action, and human rights–based legal approaches for persons with disabilities. Most countries use a variety of legal mechanisms such as constitutional law, civil rights law, and criminal law to employ and implement these differing legal approaches (Degener, 2005).

Increasingly, countries are turning to constitutional law to incorporate the human rights model of disability and articulate the recognition of the human rights of persons with disabilities in the highest law of the land. In some countries, notably South Africa, Uganda, Zambia, and Thailand (United Nations, 2011), disabled peoples organizations (DPOs) have

used constitution-building processes to leverage disability rights. Ecuador introduced a chapter on disability within its 2008 Constitution while also issuing a Presidential Executive Decree in 2007 to promote the development of disability programs across all sectors (United Nations, 2011). Kenya provides another example of constitutional change to advance disability rights and the CRPD through Article 54 in its 2010 Constitution which "seeks to minimize barriers to equalization of opportunities in all aspects of social-cultural, economic and political life" for persons with disabilities (United Nations, 2011).

Criminal laws that focus on persons with disabilities demonstrate the contradictory, complex, and varying contextualizations of disability prevalent in society. Many such laws concern persons with disabilities as victims of crime, stemming from the increasing recognition of hate crime, violence, and abuses against persons with disabilities (International Network of Women with Disabilities, 2011; Hughes et al., 2012; Piggott, 2011; Shakespeare, 2012). On the other hand, some types of disabilities, especially psychosocial disabilities, have been criminalized and penalized through laws that mandate involuntary confinement and forced institutionalizations (Perlin and Szeli, 2012; Szmukler, 2010).

Emergence of International Human Rights Law Standards on the Rights of Persons with Disabilities

The rationale for the development of a disability-specific human rights treaty was the virtual invisibility of persons with disabilities from the human rights system and the reality that an estimated one billion persons with disabilities around the world are excluded from society and are routinely denied access to education, employment, health care services, and basic needs (World Health Organization and World Bank, 2011: p. 29). Moreover, persons with disabilities are far more likely than others to live in poverty.

International human rights law did little to address the human rights of persons with disabilities prior to the adoption of the CRPD. No international human rights treaty comprehensively addressed the multitude of barriers experienced by persons with disabilities. While few states had developed disability rights law and policy frameworks, where they did have disability-related legislation, often they explicitly sanctioned disability discrimination; for example, denying persons with disabilities the right to vote, obtain an education, serve as a juror, open a bank account, own property, or work in certain sectors (Quinn, 2009). Welfare-oriented approaches to disability law and policy served to construct the development of holistic, rights-oriented legal protections (Degener and Quinn, 2002).

The UN General Assembly adopted the Convention on the Rights of Persons with Disabilities by general consensus in 2006, opening for signature by states parties on 30 March 2007. It attained the requisite 20 ratifications in short order, triggering its entry into force on 3 May 2008.

The CRPD is the first legally binding international human rights treaty to address the rights and fundamental freedoms of one billion persons and to set forth a framework for comprehensive domestic legislation to address disability rights (CRPD, 2006). The terms of the CRPD require the reform of legal systems, justice sectors, and institutions in meeting its obligations. Significantly, it goes beyond this traditional focus and brings within its ambit nonformal and decentralized justice and administrative systems and processes and recognizes the role that local communities play in rights protection and the duties of private as well as public actors in fostering inclusion (Lord et al., 2012). Its potential for shaping national disability law and policies and transforming institutions is far reaching.

The CRPD is responsive to the legal void that existed at the international level in disability law. The CRPD charts a progressive and comprehensive course for the development and reform of domestic disability law and policy in alignment with international human rights principles. It includes monitoring mechanisms intended to build the capacity of national governments, national human rights institutions, and DPOs in advancing disability rights.

UN Disability Convention Structure and Content

The CRPD comprises 25 preambular paragraphs and 50 articles. Its preamble lays out the historical progression of international standards on disability and highlights issues of importance, including the understanding of disability as a socially constructed phenomenon. The 50 operative articles in the Convention provide a comprehensive legal framework for the consideration of civil, political, economic, social, and cultural rights within the specific context of disability. It is the most detailed framing of the rights of persons with disabilities found in any treaty and serves to amplify the protections to which persons with disabilities are entitled in other, non-disability-specific human rights instruments (Kayess and French, 2008).

The CRPD has an introductory set of provisions that outline its purpose (Article 1), set out key definitions (Article 2), and articulate general articles that apply and must be interpreted and applied across provisions of the treaty (Articles 3–9). One of these general provisions is Article 5, Equality and Nondiscrimination, which prohibits discrimination on the basis of disability and requires the provision of reasonable accommodation. Article 9, Accessibility, creates obligations for accessibility in a variety of contexts. Articles 10–30 enumerate specific substantive rights of the Convention, including civil, political, economic, social, and cultural rights. The CRPD establishes a system of national and international level monitoring and implementation (Articles 31–40), and, like other treaties, contains provisions that govern its operation (Articles 41–50).

The general requirements set forth in Article 4 make clear the need to ground CRPD obligations in national law, policy, and programming, in consultation with persons with disabilities. It requires states parties to consult with and involve persons with disabilities in developing and implementing legislation and policies and in decision-making processes (CRPD, 2006: art. 4). Accordingly, the CRPD affirms the rights of stakeholders and their representative organizations to be heard, and signals recognition that participation and inclusion in decision-making is a precondition of legal empowerment.

The CRPD establishes national level monitoring requirements with three dimensions. It calls for cross-governmental coordination in recognition that disability is a cross-cutting issue, requires independent monitoring to be performed by a national human rights or disability rights institution, and calls for stakeholder participation in domestic monitoring (CRPD, 2006: art. 33). A committee on the Rights of Persons with Disabilities – the CRPDs treaty monitoring body – is tasked with monitoring implementation by states parties through its oversight of the mandatory reporting requirement and the issuance of general recommendations for the state party concerned. The Optional Protocol to the CRPD, consisting of 18 articles, gives the Committee competence to examine individual complaints with regard to alleged CRPD violations by parties to the protocol (Optional Protocol, 2006). It allows states parties to opt into participation in individual and group communications procedures and establishes an inquiry procedure, both of which are overseen by the Committee. These mechanisms are vehicles for empowering disability advocates and their representative organizations to bring complaints for individual violations as well as systemic abuses to the attention of the CRPD for review. Finally, the CRPD establishes a periodic meeting of a Conference of States Parties to consider issues relating to implementation (CRPD, 2006: art. 40). This mechanism allows state parties and disability advocates to engage in dialogue regarding implementation and best practices in law and policy reform consistent with the CRPD.

In sum, the CRPD sets forth general obligations familiar to human rights treaties – requiring national law reform and domestic incorporation of its provisions. It also provides a blueprint for national level disability rights advocacy and action. Significantly, the Convention contains a diverse set of obligations that, when surveyed, constitute a map of advocacy and empowerment opportunities at the local, national, and international levels. In so doing, the CRPD plots a course for a human rights practice that goes beyond traditional, top-down law reform-oriented approaches to embrace legal empowerment and transformation that is locally driven, community focused, and civil society oriented (Lord et al., 2012).

Translating International Standards into National Legislation

Although more than 130 countries have enthusiastically supported, ratified, and signed the CRPD, many face challenges in implementing the Convention due to disempowering social contexts for persons with disabilities and underdeveloped legal systems. This reality raises a variety of issues, among them the varied perspectives on the nature and definition of disability, and the differentiation between developed and developing countries in capacities for implementation and distinctions in approach to domestic legislative reform to bring about human rights implementation. These challenges are considered in turn.

Defining Disability in Law

Defining disability in law and policy is complex and no universal definition exists. Even within a single legal system, a multitude of definitions may be used to define disability in discrete contexts. Defining disability is highly relevant for identifying the class of individuals for whom disability rights protection is accorded. The CRPD does not provide a concrete definition of disability, but states that "persons with disabilities include those who have long-term physical, mental, intellectual or sensory impairments which in interaction with various barriers may hinder their full and effective participation in society on an equal basis with others" (CRPD, 2006: art. 1). As such, the understanding of disability in the CRPD sets a baseline, from which states may expand disability rights protection to cover, for instance, disability discrimination in the case of an individual who is temporarily disabled.

The CRPD makes clear that the term 'person with disabilities' in the Convention 'includes' individuals with long-term impairments and thus 'persons with disabilities' may indeed encompass a broader category of persons at the national level. Further, impairments are referred to in the CRPD as 'physical, mental, intellectual, or sensory' in recognition that disability is diverse with the implication that legislation must provide protection to disabled persons whatever their impairment be. Legislation excluding a given category of individuals with disability from protection, for instance, voting exclusions based on mental disability, is prohibited (CRPD, 2006: arts. 1, 12, 29).

This conceptualization demands a shift in how policy makers have reflected on disability. For example, disability laws in some countries define disability with a finite list of observable impairments, ignoring hidden disabilities that arise from chronic or mental illness, learning and cognitive difficulty, and traumas due to accidents, and disregarding environmental and interactional issues completely (Byrnes, 2011).

Disability Inclusion in Legal Reform Assistance

The provisions and motivations under Article 32, which covers international cooperation, promote the potential for state parties to assist one another with challenges in crafting required innovations and facilitating access to resources as an aid in implementation (Guersey et al., 2007). Promoting the international exchange of technical knowledge and best practices, while providing resources for capacity building, is intended to aid government workers and development practitioners in their efforts to ushering in improvements to and reforms of policies, programs, and practices. Addressing disability in international aid and development funding and support will assist low- and middle-income states parties to provide far-reaching and inclusive programs that meet their goals and obligations under the CRPD.

The barriers faced by persons with disabilities in developing countries restrict their access to information and awareness of their rights, a situation also faced by persons living in poverty and other disadvantaged groups in these countries. As emphasized in the *World Report on Disability*, persons with disabilities are likely to live in poverty and are often restricted in their access to education, employment, transportation, and health care; and often live in isolation from the wider community (World Health Organization and World Bank, 2011: p. 39). The social determinants of legal empowerment, therefore, are severely restricted for persons with disabilities. The need for awareness-building initiatives, including legal literacy programs,

participatory human rights education tied to action at the local level, legal aid bureaus, and inclusive development programming aiming to integrate persons with disabilities into mainstream programming (such as health, economic development, democracy and governance, and education) are important and implicit in the CRPD framework.

Preconditions for Law Reform

Disability awareness-raising is recognized as a core precondition of legislating for disability rights (CRPD, 2006: art. 8). As with other marginalized groups, persons with disabilities were generally excluded from participating in early disability law and policy efforts. As a result, numerous disabled people's organizations are now focusing their attention on building an understanding of legal rights and, more specifically, how to claim these rights through legal action (Golub and McQuay, 2001).

The CRPD recognizes in Article 8 that combating stigma and stereotyping rooted in disability discrimination is essential to laying a foundation for effective law and policy change (CRPD, 2006: art. 8). The focus is on disability awareness to create a culture of legal equality combined with explicit legal mandates to require public consultation as well as accessibility measures in the context of law and policy making.

Legislating Disability Rights

Many of the concepts set forth in the CRPD require states parties to bring about law and policy reforms (or the development of disability law and policy) to align with the shift to the human rights model required by the CRPD. This shift in framework presents challenges whilst creating opportunities for progressive change and legal innovation (Kanter, 2007). The requirements for legal reform to align with CRPD obligations hinge on the application of treaties with the domestic legal system of a country. It also depends upon the general state of the domestic legal framework in relation to its recognition of disability rights.

Some legal systems mandate legislative enactment to incorporate an international treaty into the domestic legal order (e.g., United Kingdom, New Zealand). In some countries, however, treaty obligations assume legislative supremacy and are automatically part of the national legal order on ratification (e.g., Argentina, the Netherlands). In other countries, elements of both approaches are evident in that some standards are self-executing and do not require additional domestic action to be enforceable, while other standards require legislative action or need clarification to be domestically enforceable.

Law review and reform play a significant role in all these systems. The CRPD requires states to undertake the following actions in the context of law reform: (1) states parties must adopt all appropriate legislative, administrative, and other measures for the implementation of the CRPD; and (2) states parties must adopt all appropriate measures, including legislation, to modify or abolish existing laws, regulations, customs, and practices that constitute discrimination against persons with disabilities (CRPD, 2006: art. 4).

The general obligation in the CRPD to give effect to its provisions in the domestic legal order implies the undertaking of comprehensive legal review in order to assess alignment with the treaty. Where gaps or inconsistencies appear, such review exercises identify areas requiring corrective measures in the form of legal development or amendment (Lord and Stein, 2008). That is to say, treaty implementation requires amendment of laws that are inconsistent as well as measures to put into place additional laws to advance implementation. The starting point for such review generally is an assessment of (1) the Constitution; (2) existing antidiscrimination legislation, whether disability-specific or general in scope; (3) existing comprehensive disability rights legislation, such as a national disability law; and (4) human rights acts.

The CRPD does not specify the precise format of implementation and thus allows an amount of flexibility, given the variation in legal systems and legislative frameworks among state parties. There are options that states may consider; for example, comprehensive nondiscrimination legislation that includes protection from discrimination on the basis of disability in one or many spheres, or a comprehensive disability rights law that addresses protection from disability discrimination as well as other types of measures. Equally, a state might introduce reforms and additional measures in discrete areas; for instance, reforming electoral codes and employment law together with new legislation to address gaps in education, transportation, or other areas to bring about wholesale change. In most instances, a combined approach will be necessary to produce full compliance and alignment with the obligations of the CRPD.

In view of the fact that the CRPD is a far reaching instrument and given that disability is a cross-cutting issue with relevance across a legal framework, a legal review will entail an assessment of a range of legislation, beyond disability-specific legislation or human rights legislation (Lord and Stein, 2008). Legislation may be usefully grouped into three categories of particular relevance for disability rights assessment: (1) Legislation of a disability-specific nature, such as a comprehensive national law on disability or an inclusive education statute or a mental health law; (2) legislation that relates to all persons or general groups of persons, but which may make particular reference to or provision for disability, such as antidiscrimination law, social security law, guardianship laws, education laws, criminal codes, or electoral codes; and (3) legislation that does not address persons with disabilities, but which is relevant to persons with disabilities, such as tax laws, construction laws, family laws, intellectual property laws, and banking and contract laws.

Finally, legal assessment for the purpose of disability law reform requires the participation of persons with disabilities and their representative organizations, as recognized in the CRPD (CRPD, 2006: art. 4(3)). In this sense, the process of law reform is fundamental to its outcome. The lived experience of persons with disabilities provides a sound basis for law and policy reform that is responsive to the specific needs of individuals and offers the best chance for human rights implementation (Blanck, 2014).

Conclusion

The first decade of the twenty-first century marked a transformative period in the progressive development of disability law, both at the international level as a consequence

of the drafting and adoption of the CRPD, and at the national level, as the result of significant reforms in domestic disability law. This period has witnessed a number of notable changes at the domestic level, where disability is emerging as a salient human rights issue and the rights of persons with disabilities are increasingly understood as worthy of attention and protection. Notable are constitutional law developments in countries where disability is a prohibited ground of discrimination and efforts across the world to adopt comprehensive disability antidiscrimination laws. The drafters of the CRPD recognized that, throughout the world, national disability law and policy frameworks were underdeveloped or, worse, contained explicitly discriminatory provisions that strip persons with disabilities of their rights. Several countries have focused their attention on adopting sign language as a national language in legislation. Others are working to modify guardianship laws to comply with the supported decision-making framework and legal capacity provisions of the CRPD. Still other countries are reviewing electoral codes and Internet usage, implementing regulations to enhance their accessibility for persons with disabilities. Advocates are likewise challenging outmoded national laws before domestic and regional courts, making claims about discriminatory educational systems that segregate students with disabilities and provide them with inferior education or challenging policies of institutionalization that inhibit the social inclusion of persons with disabilities. In the light of these recent progressive developments and growing adoption of the CRPD, the dynamic pace of disability law reform and legal development shows little sign of slowing.

Law and Risk

This article is a revision of the previous edition article by A. Bora, volume 12, pp. 8470–8474, © 2001, Elsevier Ltd.

Abstract

The issue of risk regulation arises in several areas of law. Risk regulation figures prominently in the area of environmental law, which deals with risks created by discharges of pollution. Although it is often not acknowledged, risk also has a role in criminal law, including (as discussed in greater detail below) how to balance the risk of convicting an innocent person against the risk of releasing a guilty one. This article will first consider risk in contradistinction to uncertainty, and will canvass various types of risks that societal actors face. Second, it will discuss private and public responses to risk. Third, it will examine types of public regulation enacted in response to risk. The fourth part will discuss the role various branches of government play with respect to risk regulation. Fifth, the article will consider paradigmatic risk analysis and risk management, the role of experts, and the role of public opinion in setting a risk regulatory agenda. Finally, it will discuss the precautionary principle, a normative principle grounded in concerns over risk that has been ascendant especially in the international legal arena.

The issue of risk regulation arises in several areas of law. Risk regulation figures prominently in the area of environmental law, which deals with risks created by discharges of pollution. Although it is often not acknowledged, risk also has a role in criminal law, including (as discussed in greater detail below) how to balance the risk of convicting an innocent person against the risk of releasing a guilty one.

Our discussion will first consider risk in contradistinction to uncertainty, and will canvass various types of risks that societal actors face. Second, it will discuss private and public responses to risk.

Our discussion will then focus on public regulation in response to risk. The fourth part will discuss the role the three branches of government play with respect to risk regulation. Fifth, our discussion will consider paradigmatic risk analysis and risk management, the role of experts, and the role of public opinion, in setting a risk regulatory agenda. Finally, it will discuss the precautionary principle, a normative principle grounded in concerns over risk that has been ascendant especially in the international legal arena.

What Is Risk?

Risk arises when there are multiple outcomes to which one might be subject. No single outcome will occur with certainty. Rather, each outcome – and therefore the payout associated with it – will arise with a certain probability.

Economists contrast 'true risk' with uncertainty. When we face risk, we do not know with certainty the outcome, but we do know the probability distribution of possible outcomes. In contrast, uncertainty arises when we do not even know the probability distribution of the possible outcomes (Knight, 1921: pp. 19–20). Because of limitations on our knowledge and understanding, global warming is often said to present great uncertainty, rather than simply risk. In practice, it may sometimes be difficult to know whether one really faces risk or uncertainty; many legal discussions conflate the two concepts.

The fact that, in a situation of risk, we know the probability distribution of possible outcomes means that we can calculate the 'expected value' of the risky scenario. The expected value equals the sum, for all possible outcomes, of the product of (1) the payout (whether positive or negative) from that outcome and (2) the probability that that outcome will come to pass (Nash, 2013: p. 1285). This cannot be done in the face of uncertainty.

Risk may arise in many different contexts. Engaging in certain activities may give rise to risks: For example, driving subjects drivers, passengers, and pedestrians to the risk of bodily harm, while investing in stocks and bonds may subject investors to economic risk. Economic cycles may subject businesses to risks. Contact with certain toxic substances may subject people to health risk. Nature in its extremes (e.g., hurricanes, droughts, or floods) may also put certain people at risk, if they live in the affected geographic area.

Note that different societies may assess the extent and importance of the same risk very differently. For example, the EU generally sees genetically modified organisms to pose a greater risk to human health than does the US. On the other hand, the US takes a more cautionary approach with respect to the threat of terrorism than does the European Union (EU) (Wiener, 2003: pp. 225–230). Also, in the US but less so the EU, the risk of allowing a guilty person to go free is considered more acceptable than is the risk of allowing an innocent person to be imprisoned or put to death (Nash, 2012: p. 199). Indeed, discussions and analyses of risk often raise complicated questions of morality (Ericson and Doyle, 2003: pp. 1–9).

To be sure, these differences in approaches to different risks appear in formal law. However, it is very likely that they indicate the existence of, and indeed emanate from, different cultural conceptions of what is risk and how best to respond to it. Indeed, recent studies confirm that, even within a single country, an individual's cultural values inform that individual's perceptions of risk (see, e.g., Kahan and Braman, 2006).

How Can the Law Deal with Risk?

The law takes different approaches to the various kinds of risk that societal actors face. The first option is to do nothing at all. This leaves the risk in the hands of those who bear it. In turn, those who bear risk face a number of alternatives. The first is for the societal actor to accept some combination of (1) reducing his or her (or its) exposure to the risk in question, and (2) bearing the downside of the risk if that comes to pass. Another alternative is for the societal actor to obtain insurance from a private provider. An insurer agrees to accept an insured's risk in return for payment based on the expected value of the risk and some premium. An insurer is able to take on risks from numerous insureds provided that the risks are sufficiently diversified; risks that are diversified are highly unlikely to produce extreme negative outcomes at one time (Masur and Nash, 2010: pp. 417–418). (Note that private insurers are also subject to government regulation.)

A second government option is to require societal actors who face a certain kind of risk to show the financial ability to cover a risk should a bad outcome in fact occur. For example, the US federal Resource Conservation and Recovery Act and the regulations thereunder require owners and operators of facilities that treat, store, or dispose of hazardous wastes to demonstrate 'financial assurance' for – that is, that there will be sufficient funds to cover – closure and postclosure care of their facilities, the clean up of any accidental releases of hazardous materials, and compensation to third parties for any resulting injury or property damage. Financial assurance may come in different forms, including bonds and private insurance (see *Code of Federal Regulations*, tit. 40, pt. H). In other cases, the law specifically calls for private actors to obtain private insurance. This has generally been the case for US automobile drivers and owners of nuclear plants, and now in the US is the case for health insurance under the Affordable Health Care Act.

A third government option is to provide government-backed insurance. This may come to pass where private insurers are loath to insure the risk in question, perhaps because the risk is nondiversified. For example, as a prerequisite to obtaining a mortgage backed by a federal agency on property located in a flood zone, one has to obtain government-issued flood insurance.

A fourth government option is to mandate disclosure of information pertinent to the risk – perhaps both as to the likely outcomes and the scope of possible downside scenarios. This empowers societal actors to make more knowledgeable decisions about whether to expose themselves to risks, and about those risks to which they ought to accept, and decline, exposure. The US federal government has taken this approach with respect to investment risk under the federal securities laws (Nash, 2010: p. 1030).

A fifth government approach is to use ex post liability regimes to create incentives to reduce risks. For example, tort law often imposes absolute liability on property owners who use their property in inherently risky ways.

A sixth approach is government regulation that tries to limit risk ex ante. These regulations are often promulgated by government agencies. Examples include environmental, health, and workplace safety regulations. The ex ante regulatory approach to risk has grown substantially over the past few decades (Section Paradigmatic Regulatory Risk Analysis and Management below discusses how regulators deal with risk.)

A final option is to have the courts assess a risk and then enter a ruling that deals with the assessed risk according to a governing legal rule. As one example, criminal courts in common law countries generally hold bail hearings and decide whether to grant bail – and, if so, at what amount to set bail – based upon the defendant's risk of flight or danger to the community. For another example, in deciding whether to grant a plaintiff's request for a preliminary injunction, a court will consider (among other things) the risk of irreparable harm to the plaintiff if the injunction is not granted (Nash, 2013: p. 1317).

Branches of Government and Risk Regulation

The US system typically divides government into legislative, executive, and judicial branches. What role might we expect each branch to play in risk regulation?

The legislative branch conceivably can put in place ex ante procedures, or ex post liability rules that create ex ante incentives, regarding risk. In practice, however, the legislature may be reluctant to enter the risk arena directly – perhaps especially with respect to ex ante procedures – fearing that a lack of expertise may generate ineffective and/or undesirable laws. Instead, the legislature may see fit to delegate power to an agency (either within the executive branch or independent of the political branches) to regulate as it sees fit (within the confines of legislation).

In turn, agencies that receive regulatory power from the legislature then undertake risk regulation. The discussion in Section Paradigmatic Regulatory Risk Analysis and Management below details how agency regulators typically proceed with risk regulation.

At the federal level, regulatory action by executive branch agencies is also subject to the strictures of Executive Orders issued by the President (see, e.g., Executive Order 12866, Regulatory Review, 58 Fed. Reg. 51735 (30 September 1993) (Clinton era Executive Order establishing principles for, among other things, risk assessment)). Compliance with Executive Orders is overseen by a unified executive branch regulatory office within the White House – the Office of Management and Budget's Office of Information and Regulatory Affairs (see, e.g., Percival, 1991: pp. 182–184).

At times, decisions that may have impacts on risk must be made quickly by agencies charged with enforcement. For example, police may have to decide whether to storm a location with the goal of apprehending a hostage-taker and free hostages, but at the same time putting at risk police and the hostages.

The judicial branch may use the common law process to put in place rules that implicate risk. More commonly today, the legislature may empower the courts to hear challenges to risk regulations issued by agencies.

Should Government Respond to Public Perceptions, or Expert Analyses, of Risk?

As the discussion in Section Paradigmatic Regulatory Risk Analysis and Management below elucidates, the approach to risk regulation that currently dominates in the US calls for

identification and measurement of the relevant risks should be undertaken by experts in the field. Another possibility, however, is for the government to respond not to expert assessments of risk, but rather to public calls for risk regulation.

Proponents of risk regulation based on expert risk assessment highlight how lay people tend to wildly overestimate some risks and to wildly underestimate other risks. For example, many believe that the public (or many members of the public) tend to overestimate the risks associated with vaccinations, but to underestimate the risks posed by radon gas in basements. Thus, proponents of expert-based risk regulation conclude, lay-based risk regulation will be based not on actual risks, but rather on *public perceptions* of risk. Along similar lines, they highlight that, insofar as they are not grounded in reason and evidence, people's risk perceptions are likely to be highly malleable, and thus subject to special interests groups' efforts to mold them as they see fit.

In response, proponents of a role for the public in risk regulation point to the importance of the democratic process in governance. For one thing, government ought to be responsive to people's needs. For another, government risk regulation that takes into account public opinion will have greater legitimacy.

One intermediate version of risk regulation that shows up in some US regulatory regimes is to allow the government agency to propose regulations as it sees fit, presumably based upon expert risk assessment. Then, however, the legislature empowers private societal actors to file suit in court to compel the regulator to add to its regulatory agenda (Biber, 2008: pp. 466–467). Note that such a regime may screen out situations where the societal actor lacks evidence of the existence of a real risk; the court may require such evidence before awarding the petitioning private actor the relief it seeks.

The EU also employs risk assessment methodology. Although EU risk assessments have generally tended to be more qualitative than quantitative (as compared to the US approach), there seems to be growing convergence between the two (see Wiener, 2004: pp. 82–83).

Paradigmatic Regulatory Risk Analysis and Management

This section provides a somewhat stylized summary of how government regulators respond to risk and uncertainty. (This discussion draws on the discussion in Nash (2008): pp. 498–504 and Nash (2012): pp. 192–197.) The paradigmatic regulatory approach to risk divides risk analysis into two components: risk assessment and risk management. Risk assessment goes to the question of the extent to which there is a risk. Risk management, in contrast, asks how best to respond to that risk. The justification behind this distinction is a perceived dichotomy between the types of questions that risk assessment is designed to address and those that risk management is designed to address. The question of the extent to which an activity or the use of a substance poses a risk is viewed as a matter that is appropriately resolved using the best available science. In contrast, the question of how best to respond to the existence of some risk is viewed as a policy question. Risk assessment thus seeks to isolate scientific inquiry from a balancing of policy concerns. According to theory, only after risk assessment reveals a risk should risk managers be called upon to decide what, if anything, to do about that risk.

The recommended dichotomy between risk assessment and risk management means that different actors should resolve these questions, even if both sets of actors are experts in their respective areas. Experts – with different areas of expertise – are called upon to perform each task.

Risk Assessment

The dominant US approach calls for risk assessment to be guided by science – often described in statutes as the 'best available' science (see, e.g., Executive Order 12866, Regulatory Review, 58 Fed. Reg. 51735 (30 September 1993) (Clinton era Executive Order establishing principles for, among other things, risk assessment)). Thus understood, risk assessment calls for analysis of risk both as scientifically as possible – and, implicitly, as objectively as possible.

Peer review further bolsters an agency's scientific analysis and conclusions. Courts, in turn, afford great deference to agency decisions that rest upon scientific analysis. One effect of this approach is to reduce the likelihood that government will respond to people's perceptions of risk, as opposed to what is – at least according to the dominant view – scientifically and objectively established as risky.

Risk Management

After risk assessment is complete, the analysis shifts to the more policy-centered stage of risk management. The fact that risk management is policy-driven does not mean that there is an absence of general guidelines to which some risk managers might turn (or at least that some people believe ought to guide risk managers).

First, some statutes (as well as US presidential executive orders) call on agencies to employ cost–benefit analysis in promulgating regulations. In the case of a risk-based regulation, this would call upon the regulator to consider the benefit of the regulation (which on a typical metric would be the expected value of the risk that will be avoided by virtue of the regulation) against the societal costs that the regulation would impose. Thus, for example, it might be costly for industry to comply with an environmental regulation. That cost is imposed on society (and indeed might largely be passed along to consumers in the form of higher prices or fewer products). On the other hand, the regulation will reduce health risks. A cost–benefit analysis approach asks regulators to monetize those health benefits, and to compare them to the costs the regulation would impose. A strict cost–benefit analysis would direct that the regulation not be implemented unless the benefits outweigh the costs. A weaker form of cost–benefit analysis, recognizing the difficulties in both identifying all of a regulation's benefits and monetizing those benefits, allows for the implementation of regulations provided that the anticipated costs do not swamp the anticipated benefits.

Second, risk managers may undertake 'risk–risk analysis' (Graham and Wiener, 1997). Risk–risk analysis calls upon regulators to balance the risks that a proposed regulation will reduce against the risks to which regulation itself may give rise.

It rests upon the recognition that in general one does not simply succeed in reducing risk; instead, one may often in practice 'trade off' a reduction in one risk for an increase in another. For example, in deciding whether to engage in a high-speed car chase to try to apprehend a fugitive, the police (implicitly) balance the risk of allowing the fugitive to go free against the risk of injury to the police, the fugitive, and innocent people that might result from the high-speed car chase (Nash, 2012: pp. 214–215). Indeed, the police administration in advance might offer general directives to police officers as to how to proceed in general in such situations, and police officers faced with a high-speed chase might have to apply those directives and make quick risk–risk analytic trade-offs quickly and under considerable duress.

As another example, an environmental regulation might, if implemented, reduce health risks. However, complying with the regulation will be costly to industry, perhaps because it increases the cost of the production process. That additional cost might result in higher prices to consumers (which itself might impose risks on society if, for example, the product in question is medicine) or might result in the loss of jobs (which also might impose additional risks on society because unemployed individuals might have inferior, or no, health insurance).

The Precautionary Principle

What if risk assessors cannot establish a risk with any real degree of certainty? Perhaps, for example, scientific understanding is too primitive to provide a solid basis for analysis. Here, some policy advocates – perhaps especially in the area of environmental law – advert to the precautionary principle. In essence, the precautionary principle calls for a cautionary approach in the face of risk and uncertainty, although as the discussion elucidates below, there is considerable contention over what exactly the principle means and demands.

Commentators have pointed out the precautionary principle's lack of clarity. Indeed, commentators have identified no fewer than 19 interpretations of the principle (Wiener, 2002: p. 1513). For example, a weak form of the principle authorizes government regulation where there is uncertainty. A stronger form *mandates* regulation under conditions of uncertainty. A stronger form still imposes a burden of proof on one who wants to introduce into use a substance, the health consequences of which would be uncertain to show that the substance will not pose unduly large risks (see Geistfeld, 2001).

Commentators have also criticized the precautionary principle as inherently self-contradictory, and therefore indeterminate. The argument proceeds that the precautionary principle's logic applies not only to the risk that exists absent regulation but equally to the countervailing risk to which regulation may give rise – that is, to the risk that regulating false positives may create. Thus, taken to its logical extreme, the precautionary principle would 'bring valuable activities to a halt', and would 'be impossible' to apply broadly (Wiener, 2003: p. 224).

In the face of this lack of certainty and criticism, some commentators have endeavored to rescue the principle from ambiguity and contradiction by identifying a 'heartland' area of clear applicability for the principle. The precautionary principle's 'heartland' extends to situations where (1) 'the risks of harm are uncertain'; (2) 'harm might be irreversible and what is lost is irreplaceable'; and (3) 'the harm that might result would be catastrophic'. (see Posner, 2004: p. 148, calling for "a modest version of the precautionary principle" in cases of catastrophic risk that would "plac[e] a thumb on the cost side of the cost-benefit analysis"); Sunstein, 2006: p. 894 ("It is possible to combine a concern about catastrophe with a focus on irreversible harm in a way that generates an Irreversible and Catastrophic Harm Precautionary Principle."; Nash, 2008: pp. 502–504. Sometimes, however, the risks on both sides may meet these criteria, in which case the 'heartland' applicability of the principle will provide little guidance.

At the international level, the principle has attained quite a bit of caché. Its importance is evidenced by its inclusion in numerous international statements of environmental law and international and multilateral environmental treaties. Some assert that the precautionary principle has acquired the status of customary international law. The frequency with which the principle is quoted in documents, laws, and treaties of the EU and its member states illustrates that the EU in particular believes strongly in the principle (Nash, 2008: p. 499).

With some exceptions, US domestic environmental law has not embraced the precautionary principle. This does not mean, however, that the United States does not act in accordance with the principle in other areas. The question is more one of identifying those risks that each sovereign deems to be worth addressing with a precautionary approach. Thus, for example, while the EU and its member states may follow the strictures of the precautionary principle more closely and more often than the United States with respect to environmental risks, the United States adopts a more precautionary approach more than does the EU with respect to the risk of convicting the innocent and of risks posed by terrorism (Sunstein, 2007: pp. 515–516; Wiener, 2003: pp. 225–230).

Conclusion

Legal responses to risk depend heavily upon what goals society seeks to obtain. One approach is that the law should try to minimize the risks that people perceive to exist. To the extent that, as growing empirical evidence shows, culture strongly affects risk perceptions, this will mean that different societies – and indeed different segments within a society – may call upon the law to do different things.

Another possibility is to turn to experts to determine which risks exist, and how best to deal with those risks. Paradigmatic risk analysis takes that approach. More nuanced risk analysis also recognizes that it is natural, but also generally wrong, to think that one can simply reduce a risk and thus unilaterally increase certainty and safety. Instead, the better approach is to concede that reducing one risk likely increases another; the question then becomes how best to balance competing risks.

While particular laws may respond to different risks in different ways, overarching principles offer some guidance and may provide hope one day of greater harmony in risk regulation. The precautionary principle is one such example. The

precautionary principle is quite prominent on the international legal stage, and in some parts of the world – perhaps most notably the EU. Despite its high profile, the principle suffers from a lack of clear definition, and from claims that it often can be interpreted to offer inherently contradictory advice. Still, commentators work to identify an acceptable 'core' of the principle, believing that it may one day develop into a consistent, useful guidepost for appropriate risk regulation.

Abstract

The study of law and society is characterized by a multidisciplinary approach to understanding the interaction between legal institutions and our everyday lives. Researchers may use a variety of theoretical approaches (e.g., conflict theory, feminist legal theory, functionalism, critical race theory) and methodologies (e.g., survey research, experimental methods, historical analyses, comparative approaches) to study the intersection of law and society. Many areas of study fall under the broad umbrella of law and society, including (but not limited to) exploring legal actors in the criminal justice system, status differences, attitudes about the law and examining assumptions underlying legal decisions.

Introduction and Overview

Law and society encompasses a variety of approaches to studying the interaction between legal systems and our society. Scholars who study law and society typically come from sociology, psychology, anthropology, law, economics, political science, and other fields. Thus, the study of law and society is an interdisciplinary, multifaceted endeavor, with no unifying theory or methodological approach, although research in law and society is generally empirically and theoretically driven (Vago, 2011).

Professional Organizations

There are a variety of professional associations that provide an academic and professional home for law and society research and researchers. Among them are the American Psychology-Law Society, the Society for Empirical Legal Studies, the American Law and Economics Association, the Association for Political and Legal Anthropology, and the flagship law and society organization, the Law and Society Association (LSA). LSA was founded in 1964 and currently has approximately 1600 members, an annual conference, journal (*The Law and Society Review*), and newsletter. However, law and society research may appear in a variety of journals, including the *Australian Journal of Law and Society*, the *Canadian Journal of Law and Society*, the *International Journal of the Sociology of Law*, the *Journal of Empirical Legal Studies*, the *Journal of Law and Society*, the *Journal of Law and Policy*, the *Journal of Law and Social Inquiry*, the *Journal of Social and Legal Studies*, the *Journal of Law and Human Behavior*, and *Law and Contemporary Problems*, among others (Freidrichs, 2012).

Within LSA, members can belong to a variety of collaborative research networks (CRNs), which are designed around a research area of interest to encourage international and interdisciplinary research collaboration. There are currently 44 CRNs in LSA, including CRNs on African Law and Society; Civil Justice and Disputing Behavior; Law and Health; Law and History; Lay Participation in Legal Systems; Legal Geography; Gender, Sexuality and Law; Islamic Law and Society; Teaching in Law and Society; and many others. For a full list of CRNs, descriptions, and contact information for the CRN coordinators, see www.lawandsociety.org.

Research

Law and society scholars study the law as it relates to other social institutions and entities. That is, law and society scholars ask research questions exploring how law affects society's social structures and systems, relationships between individuals and between individuals and institutions, and institutions within society. Conversely, law and society scholars also explore the reverse relationships: how our society's social institutions, structures, relationships, systems, legal actors, and individuals influence the creation of our legal system, law, and policies. Scholarship may focus around the functions and dysfunctions of law in society; the development and impact of law and lawmaking (judicial, legislative, and administrative lawmaking); the actions, roles, and decisions of various legal actors and groups (judges, attorneys, police officers, juries), describing legal systems and the role of legal systems in a larger society, the globalization of law, and the impact of policies and reforms on society.

Given the diversity in research interests, methodological approaches, and theoretical perspectives, the unifying theme is that law and society scholars recognize the importance of an interdisciplinary approach to understanding and studying the law (www.lawandsociety.org) and share the general assumption that the law has to be considered as a product of our collective historical, political, economic, cultural, and psychological contexts. In turn, the law also can impact each of these areas (Friedrichs, 2012).

We will first review a selection of functions of law that law and society scholars may study. Then, we will review major theoretical perspectives scholars use in studying law and society, followed by a sample of the research areas law and society scholars explore. We should note that a complete review of theory and research is not practical given the constraints of this article and the broad nature of the field, nor is it the intention of this article. Our discussion of theoretical perspectives and research areas is intended to provide a sample of the theory and research in law and society scholarship.

Functions of Law

Law and society scholars highlight many functions of law, and there is not general agreement in the field on a complete list of

functions of law or the importance of identified functions (Vago, 2011). There are both positive and negative functions of law (Friedrichs, 2012). From a positive viewpoint, the law maintains order, settles disputes, allows for social change or catharsis, promotes justice, promotes desirable social values, and administers practical needs to a society. From a negative viewpoint, the law can function to maintain the status quo (even if the status quo is outdated or inconsistent with a society's values), divide people, exploit people, promote conflict and violence, promote oppression and greed, or further the power of the state (Friedrichs, 2012).

The literature has focused mainly on the positive functions of law as a mechanism for social control, dispute settlement, and social change (Vago, 2011). As one of many mechanisms for maintaining social control, the law is a method used by society to maintain order and delineate which behavior is acceptable and unacceptable (Vago, 2011). The law is a formal means of social control, meaning that it has explicit rules for behavior, including sanctions for those who violate those rules and people who create, enforce, and interpret the rules (Vago, 2011).

As a mechanism for dispute settlement, the law provides a formal forum in which individuals or organizations, including governmental entities, can solve conflict in a formal, orderly manner. Resolving disputes in the legal system is a transition from the two parties resolving the dispute among themselves (e.g., by choosing to avoid the situation or informally compromise) to using a third party who is outside the original dispute to help resolve the conflict (Vago, 2011). Most disputes are resolved without the help of the legal system. Dispute resolution within the legal system typically involves resolving the legal issues in the conflict rather than addressing underlying causes, which does not necessarily reduce the tension between the parties (Vago, 2011).

The law also functions to aid and create social change. Social change refers to change in our behavior indicating that people engage in activities or relationships that are different from their previous activities (Vago, 2011). Social change can be a product of many different factors that may interact with each other, including law and legal culture, political climate, economic factors, technological innovation, and structural constraints, among others (Vago, 2011). The law can both produce social change and be an object of social change (Freidrechs, 2012). The law can have both an indirect and direct influence in producing social change. In having an indirect influence, the law can change the structure of our social institutions, which in turn shapes our society. For example, requiring citizens to attend school improved the quality of workforce. The improved workforce produced social change by increasing the industrialization of society (Vago, 2011). The law can also have a direct effect in producing social change. For example, enacting prohibition laws in the United States was intended to directly shape whether people drank alcohol (Vago, 2011). Many of the various functions of law were developed and are studied in the context of several of the theoretical perspectives in law and society.

Theoretical Perspectives

Law and society scholars tend to be influenced by a broad variety of theoretical perspectives, which is understandable given the interdisciplinary nature of the field and the diversity in the areas of study. Our review of theoretical perspectives will begin with a discussion of two ideal conceptions of society that provide a context for the discussion of theorists and contemporary theories and intellectual movements in law and society that follow.

Theoretical Dichotomy

Conflict and consensus are the two general, oppositional theoretical orientations of law and society scholarship. Both are idealized typologies of society (Vago, 2011). Conflict theory suggests that law is a weapon in social conflict (Turk, 1976) and is based on the notion that social change and conflict are ubiquitous, that all facets of society contribute to social change, and that some members of society are repressed or constrained by other members of society (Treviño, 2010). Conflict theory posits that members of interest groups will attempt to use the law to their advantage and to the disadvantage of members of opposing groups. Such conflict may be economic, political, moral, ideological, or religious. Power in society is expressed as either elitist conflict, whereby one group (for example, the economically advantaged) consistently remains in power, or group conflict, whereby two or more groups (for example, the pro-choice and pro-life groups) trade power over time. From a conflict perspective, law arises out of a desire to maintain power. Conflict theory is supported in the writings of scholars, such as Karl Marx, Max Weber, Richard Quinney, Donald Black, and Austin Turk, and in the tenants of the critical legal studies (CLS), critical race theory (CRT), and feminist legal theory (FLT) movements.

Consensus theory differs from conflict theory in that it views the various facets of society as a homeostatic system of interrelated parts. Law thrives when the majority of people agree on its execution. Building consensus therefore builds a healthy, cohesive society. Whereas conflict theory views the law as a weapon, consensus theory suggests that law, "serves to mitigate potential elements of conflict and to oil the machinery of social intercourse" (Parsons, 1962: p. 58). The law must have integrity so that it remains pertinent, and it must serve the interests of the people. If law fails to serve the people, the law will lose its legitimacy. Consensus theory is supported in the writings of scholars such as Emile Durkheim, Talcott Parsons, and Roscoe Pound and in the tenants of the functionalist movement.

Individual Theorists

Emile Durkheim (1858–1917), a French sociologist and consensus scholar, stated that sociology is the study of social facts. Social facts are methods of thinking, feeling, and acting that are coercive in nature (Treviño, 2010). Law is the preeminent social fact because it is enduring and because a lawless society is undesirable. Adherence to the law is cultivated through solidarity, which may be either mechanical or organic. Mechanical solidarity exists in small, homogenous societies. Solidarity exists because people are similar and share belief systems. Organic solidarity exists in larger, postindustrial, differentiated, and heterogeneous societies. It is a more evolved state whereby individuals rely on one another due to the division of labor (Treviño, 2010). Mechanic and organic solidarity

correspond with repressive and restitutive law. Repressive law, observed in societies organized based on mechanical solidarity, delivers sanctions designed to punish because of community outrage at having violated an agreed-upon standard. Restitutive law, visible in societies organized based on organic solidarity, is meant to provide conciliatory solutions rather than punitive sanctions.

Max Weber (1864–1920) was a German sociologist who looked to religious, political, and economic influences to define and explain the law. Law, Weber states, can be either rational or irrational. He distinguishes four types of legal thought – formal irrational, substantive irrational, substantive rational, and formal rational – and notes that formal-rational legal thought is unique to the Western legal system (Treviño, 2010). Weber defines a law as a convention that is subject to three criteria – external pressures to comply, pressures that involved coercion or force, and officials in place to apply that coercion or force. If one or more of these criteria are missing, the convention cannot be considered a law. An additional Weberian contribution to law and society is his three forms of political authority – charismatic authority, or that which is innate in a leader such as a prophet; traditional authority, or that which is inherited by a leader such as a king; and rational-legal authority such as authority derived from statute as in the case of an elected official (Treviño, 2010).

Donald Black (1941–present) argues that legal scholars confuse the science of studying the law with the policy implications of legal research and the effectiveness of the laws in question (Treviño, 2010). He states concisely that law is governmental social control (Black, 1976). Deviant behavior is conduct that is subject to that social control. The more social control applied to a behavior, the more deviant it is considered. Law, according to Black, is quantifiable and can be measured. Law exists in accusatory or remedial styles. Accusatory styles of law may be either penal or compensatory, and remedial styles of law may be either therapeutic or conciliatory. More than one style may exist in a single legal conflict. Black states that the amount of law in a society is inversely related to other forms of social control in that society (for example, religious or political control). A conflict theorist, Black suggests that discrimination is inherent in the law.

Karl Marx (1818–83) believed that the function of law was to uphold our economic system. He posited the term economic determinism, suggesting that the economic structure dictated the structure of the rest of society, including the legal system. Society, Marx suggested, is composed of two groups – the bourgeoisie, who are economically dominant and own the means of production, and the proletariat, who are economically subservient (Treviño, 2010). The bourgeoisie, he suggests, use the law to maintain their economic power over the proletariat. Marx predicts that once the proletariat is aware of their condition of subservience, they will rise up and overthrow the dominant class, causing the collapse of capitalism and creating a socialist society (Vago, 2011).

Roscoe Pound (1870–1964) suggests that the function of law is to harmonize and balance opposing interests in the name of social order (Pound, 1943). He recognizes three categories of interests – individual, public, and social – but identifies social interests as the most expedient way to evaluate an issue or idea. Law, therefore, must balance social interests. According to Pound, general security is the chief social interest, followed by security of social institutions, general morals, conservation of resources, progress, and other considerations (Pound, 1943).

Richard Quinney (1934–present) may be most famous for his text "The Social Reality of Crime" (2001). Crime, he suggests, results when actions are made illegal based on the desires of the ruling class. A conflict theorist, Quinney posits that,

1. crime is a definition of conduct;
2. crime is behavior that conflicts with the interests of society's powerful;
3. the powerful have the capacity to apply criminal definitions to actions;
4. those who act in manners that are contradictory to the desires of the powerful are more likely to be classified as criminal;
5. the larger the number of actions or behaviors that are classified as crime, the more crime will exist in society; and therefore
6. crime is the creation of criminal definitions, the application of those definitions, behaviors that conform to or contradict those definitions, and the creation of criminal conceptions (Quinney, 2001).

Contemporary Theories and Intellectual Movements in Law and Society

The functionalist approach in studying law and society is rooted in a consensus perspective (Barkan, 2009; Vago, 2011). The functionalist approach historically borrowed an analogy from biology to explore the role of law in society. In this analogy, the society is considered the organism as a whole and the systems within the society (e.g., the legal system) function to maintain that organism, similar to how the parts of the body function to maintain the organism (Barkan, 2009). In this perspective, one could examine both the structure of the society as a whole (i.e., the organism) in understanding how the systems in a society relate to one another and the function of the society, or the activities of each system within the society and the consequences of those activities for the society as a whole (Vago, 2011). Thus, to fully understand a society and how law functions within that society, one has to consider all the parts of the society and how those parts relate to and affect one another. According to this approach, the law (and other social systems) can have both manifest and latent functions. Manifest functions are those that are well understood by members of the society and the intended purpose of the social system (Vago, 2011). Latent functions are the unintended consequences of those manifest functions; they often are not formally recognized.

Criticisms of functionalism include the idea that functionalism is an oversimplification of the relationships between social systems and society as a whole (Vago, 2011). In addition, what might be functional for one group of people in society may be dysfunctional for another group, exposing a status difference between various groups in the population. However, functionalism continues to be one of the most popular viewpoints in studying law and society today (Vago, 2011).

The basic tenant of the CLS movement is that the law must be considered in light of the personal biases of the individual legal actors and the social context in which people operate (Vago, 2011). That is, because one can use precedent to argue each side of a case, the law becomes more of a product of the individual biases of the decision makers and the context of the individual case rather than a product of the precedents in a case (i.e., it is indeterminate; Barkan, 2009). Thus, even though law may seem to be neutral, it is not independent of our values, politics, economics, and social systems (Barkan, 2009; Vago, 2011). Thus, the law represents an ideology that maintains the status quo in society (Barkan, 2009). In addition to examining the basis of law, CLS scholars also examine legal education, as it contributes to the problems with law discussed above (Barkan, 2009). The CLS movement has been criticized for being controversial and cynical, and the ideas within the movement are still evolving; however, it provides a useful forum for examining the legal system (Vago, 2011).

FLT (or feminist jurisprudence) is rooted in the conflict perspective, and the source of the conflict in the theory is issues of gender, inequality, and the law. The law contributes to and reflects gender inequality in our society (Barkan, 2009). According to Vago (2011), there are three central, broad, and interrelated themes in feminist legal scholarship. The first theme addresses the male dominance in the legal profession and society as a whole and women's inequality that results from that dominance. The second theme is that the law itself reflects male ideas, ideals, and culture, and therefore, feminist legal theorists must create new law that is free of those characteristics that reinforce masculine ideals (Vago, 2011). For example, male culture may trivialize problems in which women are typically victims and shirk responsibility for those problems even though men are typically the perpetrators (e.g., sexual assault, sexual harassment, domestic violence; Vago, 2011). According to feminist legal theorists, the law reflects these masculine ideas about these types of incidents. The third broad theme reveals the gender biases inherent in the law itself, showing how the law is not a value-neutral institution.

Feminist legal theorists typically use three methods for exploring problems within the broader themes (Vago, 2011), and many feminist legal theorists use historical analysis within these methods (Barkan, 2009). The first method is asking the woman question, or exploring the law for gender implications and taking into account the experiences and perspectives of women (Vago, 2011). The second method is feminist practical reasoning, or identifying how women may think differently about the law compared to traditional legal reasoning and challenging those laws that claim they represent the voice of the community but in reality reflect masculine reasoning or culture (Vago, 2011). The third method is consciousness raising, or bringing to light the common experiences of women who have been adversely affected by legal principles, thereby challenging the legitimacy of those principles (Vago, 2011). Criticisms of FLT include that it is an oversimplification of the complex relationships in law and society that result in classes of people who are mistreated in the law (and that one has to consider class, race, and ethnic background in addition to gender; Vago, 2011). In addition, the literature is not clear on some issues, e.g., whether women should be treated similarly to men or whether women should be treated differently (but equally).

CRT is a movement in law and society that examines the intersection of race and ethnicity and the legal system using a variety of disciplinary perspectives (Barkan, 2009). As such, critical race scholars explore questions of oppression, discrimination, and inequality in the legal system and the legal profession (Vago, 2011). According to CRT, one cannot fully understand law without accounting for race (Barkan, 2009). CRT scholars acknowledge that racism is institutionalized in our current legal system and work to rectify the wrongs of racism in our society (Vago, 2011). The basic premise of CRT is that minorities or persons of color are oppressed in our current culture, and because of those oppressions, they are disadvantaged and experience the world differently than those who have not been oppressed (Vago, 2011). Some CRT scholars bring to light those experiences through narratives or storytelling to expose racism (Barkan, 2009). Others explore the structure of law as a source of institutionalized (and often unconscious) racism in society. Criticisms of CRT include that race is considered a macrolevel social construction, and the theory has not explored the construction of race on the interpersonal level (Vago, 2011). In addition, there is no general standard methodology or common tenants throughout CRT scholarship; however, this can be understood, given the theory is relatively new compared to other theories (Vago, 2011).

Areas of Study in Law and Society

Research in law and society is very broad, generally encompassing many disciplinary and methodological approaches. Law and society scholars may use time-series analyses that allow scholars to assess change in behavior over time or cross-sectional studies that allow researchers to examine differences in behavior or characteristics of different samples of the population, surveys, public opinion polls, ethnographic research, historical analysis, observational methods, survey analysis, or experiments (Friedrichs, 2012). It is beyond the scope of this article to provide a comprehensive review of all research in the area. Instead, our goal is to provide examples of areas of study and research under the wide umbrella of law and society. We will discuss legal actors, testing assumptions in the law, status differences in the context of law and society research, and examining attitudes about the law (Freidrichs, 2012).

The Legal Profession and Other Actors in the Legal System

Law and society scholars have devoted much scholarship toward researching the evolution, role, and decision-making processes of various legal actors in the criminal justice system, including attorneys, police officers, judges, and juries, among others (see Barkan, 2009; Vago, 2011 for reviews). For example, in one study, James Q. Wilson (1968) found that the policing agencies generally fell into one of three styles (although styles may overlap). In the watchman style, police emphasize the importance of maintaining order within the society and informally handle many violations in favor of keeping the peace. Watchman-style agencies tend to use the

most discretion in their duties relative to the other styles. The legalistic style can be considered the opposite of the watchman style, with officers using the least amount of discretion and treating every violation (even minor ones) as serious violations of the law. The service style combines the enforcement and order maintenance functions of the police, emphasizing community relations and using a moderate amount of discretion, separating more serious infractions from more minor offenses (Wilson, 1968).

Testing Assumptions in the Law

In making decisions about what behavior is acceptable or required, lawmakers may make assumptions about how people generally behave, make decisions, or will act in a given circumstance. These assumptions are not always based on science and can lead to negative outcomes. Law and society scholars have tested many of these assumptions in their research.

For example, researchers have examined the assumptions underlying the United States Supreme Court (USSC) decision in *Daubert v Merrell Dow Pharmaceuticals* (2003). In this decision, the USSC determined that judges would be the gatekeepers of scientific testimony in the courtroom, evaluating the science for relevance and reliability to determine admissibility. However, the USSC assumed judges were equipped to evaluate the reliability of science, an assumption that research has shown to be erroneous (see Kovera et al., 2002 for a review). Further, the USSC also referenced three safeguards (cross examination, judicial instruction on the burden of proof, and the presentation of contrary evidence, including opposing expert testimony) designed to help juries make good decisions about science in cases in which junk science was erroneously admitted. Research has examined these safeguards and found that the assumption that they will help jurors make a better decision about expert testimony is also erroneous (see Levett and Kovera, 2008 for an example). Thus, examining assumptions in the law may reveal opportunities to improve the effectiveness of the law by making it more consistent with how people actually behave.

Status Differences

Typically, law and society scholars who study status differences do so in the context of one of the theoretical perspectives discussed above. Scholars have explored the law in terms of differences in wealth, race or ethnicity, gender, power, or a host of other variables (Friedrichs, 2012). The scholarship typically examines how the law is a product of and enforces the inequality between groups of people, showing how law protects the interests of the more powerful group and oppresses the disadvantaged group.

One example of work examining status differences is Jeffrey Reiman and Paul Leighton's book *The Rich Get Richer and the Poor Get Prison: Ideology, Class, and Criminal Justice* (2009). Reiman and Leighton explore status differences among people of different classes in the criminal justice system. For example, the authors show how those things we most typically legally define as crime and treat the most seriously in the criminal justice system tend to be acts that are typically committed by the poor, and other crimes that could be considered just as serious (e.g., failing to make working conditions safe resulting in death and injury) are noncriminalized and typically perpetrated by more wealthy individuals (Reiman and Leighton, 2009).

Attitudes about the Law

Law and society scholars have devoted scholarship to studying how people think about the law, and in turn, how those attitudes affect their behavior. For example, in Tom Tyler's work, *Why People Obey the Law* (2006), he distinguishes between normative (what people believe is just) and instrumental (behavior that is a consequence of incentives or penalties) perspectives on why people follow the law. While much legislation is focused on creating law to affect behavior through an instrumental perspective, Tyler shows that a normative viewpoint may actually be more important. That is, if people see the law as just and appropriate, they will automatically feel motivated to follow the law, either because of personal morality or because they view the law and legal actors as legitimate (Tyler, 2006). In addition, if people perceive the process legal authorities follow in executing the law as fair (or the procedure as just), they will be more likely to see the law as legitimate and therefore comply with the law (Tyler, 2006). Thus, peoples' perceptions of the law can influence their propensity to follow the law.

Conclusion

As a field, law and society encompasses many areas of study, disciplinary approaches, and methods. Overall, the goal is to investigate how legal rules and systems affect our lives, and how society, in turn, can affect the formation and enforcement of those legal structures.

Abstract

The article discusses the origins of the field of law and society (also called sociolegal studies), especially in the United States; relates it to 'legal realism' and to competition and cooperation between the fields of law and sociology; explores the symbiotic relationship of the field to the social welfare state; and then explains its more hostile relationship to the neoliberal state. The field grew very quickly in the 1960s in relation to the activist state, declined in relation to law and economics and the neoliberal state, and then has prospered again through globalization and the rise of interdisciplinary studies in law schools.

'Law and society' and 'sociolegal studies' refer to an interdisciplinary field represented by organizations such as the British Socio-Legal Studies Association and the US Law and Society Association, each of which developed out of a particular blending of law and social science that took place in the 1960s and 1970s in conjunction with the rise of the activist state. In the United States, a group of foundations came together to produce a field that began quite close to sociology but moved increasingly close to law. The power and prestige of this field ascended in the 1960s and 1970s, declined with the rise of economics as a challenge to the activist state, and then returned to prominence with globalization and the rise of interdisciplinary scholarship in US law schools.

Scholars who have sought to integrate law and social science have united under various banners, and the most important of these are 'law and society,' which began in the United States (Garth and Sterling, 1998), and 'sociolegal studies' (Campbell and Wiles, 1976), which began in Great Britain. More recently, 'empirical legal studies' in the United States is also used to describe those who combine social science and law.

There are scholars in many parts of the world who share these identities, but the field, even in Britain, owes much to origins in the United States. Its emergence in the United States relates to the fact that the legal profession has long held a dominant professional position in economic and state power, and social science disciplines in the United States developed very differently from their counterparts elsewhere. In the United States, the disciplines became more differentiated, more empirical, and more positivistic than in other settings. Those trained in the disciplines could challenge the hegemonic position of law in the United States, and this continuing challenge helped to produce the field of law and society. The relative success of this field in the United States made it attractive to others, including most notably the British and Canadians. The two largest organizations are the Law and Society Association (LSA) in the United States and the Socio-Legal Studies Association (SLSA) in Britain. The LSA has more than 1500 members, and the SLSA some 750. Both groups contain a diverse array of scholars, interests, and approaches. Common frames of reference include work on the legal profession, issues of gender and race, state regulation, courts and dispute resolution, and crime and criminal justice. These research topics define the mainstream of the field, which includes the full range of social science methods.

Recognizing the importance of the United States in defining the field of law and society is not inconsistent with seeing this field as part of an international phenomenon. First, there are many scholars in a number of countries, including Australia, India, Japan, Korea, and several countries of Europe and Latin America, who have been influenced strongly by, and who have contributed to, this field. The influence can be traced in part to the law and development movement in the 1960s and 1970s, which promoted educational interchange and a range of interdisciplinary work on the legal profession and the courts in particular. Notable examples include the work of Rogelio Perez Perdomo in Venezuela, Upendra Baxi and Rajiv Dhavan in India, and Setsuo Miyazawa in Japan. Much work in the law and society tradition continues to be produced by these individuals and others.

A second international influence came from the fact that participants in the law and development movement from the United States, such as Lawrence Friedman, Marc Galanter, and David Trubek, took their insights from abroad and used them to develop theories and models that could be applied to the United States. The best known of such approaches is Galanter's famous article on 'Why the haves come out ahead' (1974), which was in large part based on his experience in India.

More generally, a related but distinguishable field of 'legal sociology' took shape at roughly the same time that 'law and society' developed in the United States, and it continues to be important in Europe and elsewhere. The major institution is the Research Committee on the Sociology of Law, which is affiliated with the International Sociological Association and also meets with the US Law and Society Association every 5 years or so. One of the pioneers of legal sociology in the United States, William Evan, joined with Adam Podgorecki of Poland – then visiting in the United States – to take the initiative in 1962 to form the Research Committee. The first president was Renato Treves of Italy, who built the Research Committee as a distinct entity devoted to legal sociology. Again, while there have long been overlaps with law and society, the scholarship associated with the Research Committee is more 'European,' which can be defined as more theoretical and less empirical than that typically associated with law and society or sociolegal studies.

The development of 'law and society' in the United States occurred at almost the same time as the founding of the Research Committee, but the story begins with the legal realists, who used the growing prestige of social science and especially sociology in the 1920s to mount an attack against the formalism of the generation that controlled the legal academy at the time. Centered at Yale and Columbia Universities, the realists carried out empirical studies of the legal system and challenged the assumptions of those they labeled as 'formalists' – those who believed that the law was a self-contained system such that legal precedents actually dictated the results in legal cases. Among the prominent legal realists were Charles Clark, William O. Douglas, Jerome Frank, Underhill Moore, and Walter Wheeler Cook. Although the legal realist movement as such died by the end of the 1930s, its leaders had been absorbed into the mainstream of the legal profession, and the interest in social science had seemingly disappeared. The orientation of the realists, however, helped set the stage for later developments (see Legal Realism; Legal Formalism).

A gradual revival of the interest in law and social science after World War II generated the people and momentum to create the LSA in 1964. During this period, the Ford Foundation invested substantially in empirical projects that focused on the legal system. One major grant was to the newly established American Bar Foundation (ABF) to fund the Survey of the Administration of Criminal Justice, which was directed by Frank Remington of the University of Wisconsin. Another important grant was to the University of Chicago to support a variety of research projects, the best known of which was by Harry Kalven and Hans Zeisel on the American jury.

In the 1950s, one of the promoters of the legacy of legal realism, David Cavers, used his position as associate dean at Harvard Law School to influence a prominent alumnus, Walter E. Meyer, to provide in his will for the establishment of the Walter E. Meyer Research Institute of Law, which was to encourage law-trained researchers to use the tools of social science in their research. Once established in the late 1950s, the Institute made numerous grants over a 20-year period to help develop the field of law and society.

Even more than the Ford Foundation and the Meyer Institute, the Russell Sage Foundation's grants served to institutionalize these collaborative ventures in the 1960s. Prior to the time of the establishment of the LSA, itself promoted by the Russell Sage Foundation, the Foundation had already invested more than a million dollars in law and social science. The major investment began with a grant to the Center for the Study of Law and Society at the University of California, Berkeley, and other grants were made to establish centers at the University of Wisconsin (1962), Northwestern University (1964), and University of Denver (1964). Later in the 1960s, after the establishment of the LSA, the Meyer Institute and Russell Sage Foundation funded 6 years (1967–73) of summer institutes in Denver for legal academics in a program entitled Social Science Methods in Legal Education. The National Science Foundation program in law and social science began in 1972 and reinforced the idea that this set of topics comprised a distinctive field.

The 1960s and early 1970s represented a kind of golden age for law and social science. There was a strong relationship between what was happening in the production of knowledge and what was happening in the streets and in the civil rights movement outside of the academy. Social science provided a new professionalizing expertise that offered ways to manage the new social agenda. Sociological knowledge thus gained in value as a new generation helped to define a political agenda of concern with urbanization, race relations, poverty, and crime. This social science learning could be used to challenge the postwar complacency of law schools and the training and expertise of lawyers for governing the state.

Remaining followers of legal realism, including such figures as Cavers and Willard Hurst of the University of Wisconsin, used this rising prestige of the social sciences to renew their own attacks against legal traditionalism and formalism. As both a cause and a reflection of this challenge, a few philanthropic foundations made it their missions to build institutions that would fly the banner of this new sociological expertise. Their investments in learning and in building institutions succeeded in bringing a new expertise to law and to the activist state.

The period of relatively high prestige for scholars bridging law and social science was in retrospect relatively brief. The 1980s again brought a period of rapid social change, but social science generally, and 'law and society' in particular, declined in relative prestige. Indeed, just as law and society helped to build and legitimate the activist state (and the role of law in its construction), the competing movement of 'law and economics' provided much of the learning and legitimacy for the later turn away from social welfare and state activism.

The way that law and society linked with the activist state, and the tensions within the law and society field, can be seen in the stories of two of the Russell Sage centers – Berkeley and Wisconsin. The Russell Sage Foundation grant to establish the Law and Society Center in Berkeley in 1962 began a process that continued through the closing of the School of Criminology and the establishment of the Jurisprudence and Social Policy program at the law school in the late 1970s. Phillip Selznick was the key individual in developing the idea of the Center. Selznick's early work focused on organizations as institutions (Selznick, 1949), but he became increasingly interested in law and its relation to the normative lives of organizations. In 1969, Selznick et al. published *Law, Society, and Industrial Justice* (1969), written in collaboration with Philippe Nonet and Howard Vollmer and published by the Russell Sage Foundation. Drawing on his studies of institutions, Selznick and his collaborators examined the general institutional setting of labor–management relations, asking how 'emergent law' – including due process – could be brought to and realized in the industrial setting as 'industrial justice.' Paralleling Selznick's own move from institutionalism toward legal and even jurisprudential issues, the book asked "what it means to legalize an institution, that is, to infuse its mode of governance with the aspirations and constraints of a legal order" (Selznick et al., 1969, p. 8).

Others who joined the Center followed in Selznick's footsteps, advancing the study of law as an institution; these scholars included Sheldon Messinger, Jerome Skolnick, and Jerome Carlin. Within the law school, there was relatively limited but growing support for the Center and for sociolegal studies, in particular from Geoffrey Hazard and Caleb Foote. A new cohort of law professors, led by Sanford Kadish, began to move much closer to the Center later in the 1960s. Carlin

initially decided to focus his research on solo practitioners, and the result was a pioneering account of that world, entitled *Lawyers on Their Own* (Carlin, 1962). He moved to the Bureau of Applied Social Research at Columbia University, where he produced another major work, *Lawyers' Ethics* (Carlin, 1966). He then moved to Berkeley to work at the Center and the Sociology Department. Beginning in 1963 at the Center, his first project explored the relationship between the legal system and the class system. The project, which also involved Messinger and Jan Howard, resulted in the well-known article in the first issue of the *Law and Society Review* on 'Civil justice and the poor' (Carlin et al., 1966), and a book on the same topic. The conclusions emphasized the unequal access to law by the poor and helped make the case for the redistribution of legal services. It fitted very well with the 'war on poverty' and the ferment that was building around new legal services programs. The research connected closely to the social and legal activism of the time.

Also in Berkeley, but less oriented toward the Center, was Laura Nader, one of the few women involved in the early years of LSA and also a creator (or re-creator) of the subfield of legal anthropology. Nader's Harvard dissertation was based on fieldwork in Mexico with a focus on law cases. She joined the Berkeley Anthropology Department in 1960 with a specialty in the anthropology of law, which she then helped to develop. She organized the first major conference on law and anthropology, which resulted in a book that helped define this emerging subfield of legal anthropology. She also organized her students into the Berkeley Village Law Project, which focused on villages and 'disputing,' and became very influential in law and society as well as in legal anthropology. Legal anthropology continued to be a very live field into the 1970s, contributing to the emerging interest in alternative dispute resolution.

Eventually the Center moved into the law school, in part because of the Berkeley administration's decision to close the School of Criminology. What was left of the criminology school was merged in 1977 with the Center for Law and Society under the auspices of the new Jurisprudence and Social Policy (JSP) program. The social scientists moved to the law school. The law school, for the most part, remained dominated by the legal mainstream, but the legacy of the origins in sociology remained evident – even in the jurisprudential component of the JSP program.

Wisconsin, in contrast to Berkeley and the other centers, already had a thriving interdisciplinary community in the 1950s. It centered in the law school and was built on Willard Hurst and the legacy of legal realism. The Hurst contribution can be traced to Lloyd Garrison, the dean at Wisconsin Law School during the 1930s. At Wisconsin, Hurst worked enthusiastically with Garrison to develop first-year teaching materials for a course on 'law in society,' and he also invested substantially in the cohort of young professors in the law school. The group built an identity that helped to constitute law and society.

Following Hurst's lead, Stewart Macaulay also moved toward the sociology of law and the attack on legal formalism. Hurst also encouraged Lawrence Friedman, and many others, to write about law in the specific context of the state of Wisconsin, which led to the publication of *Contract Law in America* in 1965 (Friedman, 1965). Macaulay and Friedman teamed up to produce one of the early sets of materials on 'Law and the behavioral sciences' (Friedman and Macaulay, 1969). This Hurst-inspired group expanded in the 1960s with the law school at the center.

One of the most important individuals was Harry Ball, a sociologist recruited initially to work on the ABF Survey of the Administration of Criminal Justice. Not only was he a key person in the Russell Sage grant, but also he was one of the leaders with Robert Yegge (dean at the University of Denver College of Law) and Richard (Red) Schwartz (the first editor of *Law and Society Review*) in establishing the LSA in 1964. Along with Ball, Friedman, Hurst, and Macaulay, the law and society contingent grew to include Joel Grossman (Grossman, 1965; Grossman and Grossman, 1971), Joel Handler (Handler, 1967; Handler and Hollingsworth, 1971), Herbert Jacob (e.g., Jacob, 1965), Stanley Katz (Katz, 1971), Jack Ladinsky, Frank Remington, and others.

The Wisconsin tradition built around Hurst, which can be characterized as that of 'law as the dependent variable' or, perhaps more accurately, 'law in context,' provides one enduring approach in the field of law and society. It is characteristic of the work of Friedman and Macaulay, for example, and others from the same group such as Joel Handler. To take an example from the early days of the 'war on poverty,' Handler criticized the proposition, identified with Yale's Charles Reich, that the legalization of welfare and the provision of due process hearings would be sufficient to deliver concrete gains for welfare recipients. Criticizing the faith in legal formalism, he suggested that a careful examination of social context could make sure that the law would deliver better substance. In the writings of Hurst and other followers, the idea that law is a dependent variable was not inconsistent with idealism or an active role for law. Educated lawyers aware of social and economic contexts could make law a much more effective instrument for social progress.

Wisconsin was able to maintain a critical mass within the law school, nourished by the other departments of the university. It was able to sustain a law and society tradition that self-consciously offered a different model than that found in the elite law schools, which remained outside of the LSA orbit. The group in Wisconsin identified its approach with the LSA organization, with Friedman, Macaulay, Handler, Jacob, and Marc Galanter (who came later) all serving as presidents, and Joel Grossman serving also as editor of the *Review*.

This University of Wisconsin approach – built around law professors – both complemented and competed with the more sociological and jurisprudential orientation in Berkeley. Wisconsin's center was dominated by the law school and the personality of Hurst, while Berkeley's center was initially dominated by sociology – especially Selznick. The law professors at Wisconsin developed their approach by emphasizing in their struggles with the legal establishment that law was the dependent variable. This strategy allowed them to use social scientists and social scientific tools to attack legal formalism and the legal establishment on behalf of the concept of 'law in context.' The idea, especially in Hurst's works, was that the context was necessary to make the law more effective and better able to solve social problems.

The Berkeley sociologists, in contrast, emphasized jurisprudence and legal philosophy, which they – in particular Selznick – could see that sociology lacked. Scholars of institutions, as Selznick argued, needed to bring law to those institutions. The sociologists also could emphasize their superior training for social research. The law professors, they suggested, were incapable of making serious contributions to important theoretical questions of concern to social science, which was necessary to solve social problems. When the Berkeley sociologists and the Wisconsin lawyers found themselves on similar terrain, however, the opposition tended to turn into one between law and social science. Depending on what position one took in this competition, therefore, the sociologists at Berkeley could be seen as 'merely sociologists,' lacking any real legal expertise, or they could be characterized as 'real scholars,' in contrast to 'atheoretical' or dilettante lawyers.

The relative positions can be seen in the approaches to legalization and procedural due process. While Handler, from the perspective of law and context, based his criticism of law professors such as Charles Reich on their neglect of the social factors that would limit the impact that welfare rights and hearings would have on the lives of the poor (Handler, 1966), Selznick's *Law, Society, and Industrial Justice* (Selznick et al., 1969) emphasized due process as "the primary source of concepts and doctrines used in bringing the rule of law to new settings" (p. 274). The different approaches relate to the fact that Handler was initially using social science to challenge legal formalism, while Selznick was initially using law to show its relevance to the study of social institutions.

The same basic contrast between law and sociology was also evident in the approaches of the Walter Meyer Institute, which was closer to law, and the Russell Sage Foundation, which was closer to sociology. The LSA was initially the creation of people who, in terms of this relative opposition, were much closer to Russell Sage and to sociology. Yegge was the only law professor among the major founders, and the Russell Sage Foundation provided the initial funds. The contrasting structural positions, however, should not obscure the close proximity of these players on the emerging field. These were the lawyers closest to social science and the social scientists closest to lawyers. Even at the personal level, the protagonists were all friends and collaborators in building interest in the field of law and society. They shared a position against legal and sociological traditionalism, but they disagreed about how to define the new field of law and social science – and the relative positions of lawyers and social scientists within that field. They tended naturally to want to define the field in terms of their own expertises and approaches.

By the mid-1960s, this general field of law and social science had not only developed a number of institutions and adherents, but also served to define and build much of the expertise of the state as the war on poverty began and added further resources to the field. Many of the people intersected with the new set of state programs, and indeed the relative success of the field is reflected in the career successes of those who developed this field. At the time of the development of the LSA, in short, the expertise of law and social science – including but not limited to the LSA – was gaining legitimacy and moving rapidly into the state.

The field that was constructed and the LSA itself gradually tilted in favor of law. By the late 1960s, law had incorporated enough social science to stave off the social science challenge. This shift in the center of gravity of the field of law and social science generally was also evident in the 1970s, in the relative power within the LSA of law professors and in particular professors linked to Wisconsin. The presidents of the LSA were almost all law professors linked to Wisconsin. A later indicator of the shift in the center of gravity occurred when the Berkeley Center for Law and Society was brought into the domain of the law school. Put another way, much of the investment in the field of law and social science in the 1960s ultimately found its way into the LSA and the law schools.

The relative value of social science expertise declined in the 1980s. A know-how that served to help construct an activist state seemed to lose some of its relevance. Academic investment in economics by the mid- to late 1970s tended to pay richer legal career dividends than investment in the disciplines that were built more into the LSA. Just as bright and ambitious people were drawn to social science in the 1950s, many were drawn to economics in an era when inflation and the state were considered the great enemies of progress. Economics seemed to define the problems and the solutions for the 1980s just as sociology did for the 1960s.

Nevertheless, once established, the LSA developed its own organizational dynamic. A second generation brought up within the LSA came to define the scholarship around the LSA as a 'field' distinct from law and from the social science disciplines. The link of the LSA to the progressive politics of the 1960s also helped to give the LSA an enduring progressive political imprint.

The next group of leaders in the LSA followed an approach similar to that of the Wisconsin pioneers. Rather than emphasizing 'law and context' as an antidote to optimistic progressivism, however, the new generation – many educated at Wisconsin by the pioneers – took aim at the politically leftist legal scholars of the critical legal studies movement and suggested that they needed more social science to understand and substantiate their leftist critiques. The 'Amherst seminar,' which produced much of the LSA leadership in the 1980s (including Austin Sarat, Susan Silbey, Sally Merry, Christine Harrington, Barbara Yngvesson, Patricia Ewick, and Kristin Bumiller), showed how the 'constitutive' nature of law prevented the social change that had been sought in the 1960s.

As an ongoing organization with both established scholarly tools and an openness to those looking for an identity to challenge the legal mainstream, the LSA continues to thrive as an organization many decades after it was founded. The tensions and hierarchies present at its creation, however, continue to play a prominent role in shaping the organization and the field that it represents. The establishment of the Society for Empirical Legal Studies in 2005 is in part a reflection of those tensions – carving out a place for those emphasizing quantitative research of practical use to lawyers and courts.

Late in the 1990s, in addition, the field renewed the commitment to internationalization that characterized it in the 1960s and 1970s. There is a new law and development movement anchored in places such as the World Bank that adds momentum to the internationalization of the field. With unprecedented educational interchange both in the social

sciences and in law, in addition, the US-centered field is opening up to many scholars from outside the United States. Much of the growth of the LSA in recent years, for example, has come from its international membership. The 'collaborative research network' of the LSA that focuses on East Asia, for example, is sufficiently large to have its own conferences in Asia.

Globalization and the rise of interdisciplinary legal studies have brought renewed importance to the field of law and society, also called sociolegal studies. There are competing organizations that have somewhat different orientations, but the different groups take into account each other's work and approaches.

Abstract

The conclusion of the Agreement on Trade Related Aspects of Intellectual Property Rights (TRIPS Agreement) in 1994 established a minimum baseline for regulating access to technology and knowledge goods. This global regime of intellectual property rights has since been a contentious aspect of modern economic relations. It has been viewed by consumers around the world as a significant barrier to access to technology and associated knowledge goods, including stymieing opportunities for social and political engagement by citizens. Public disenchantment with intellectual property as a primary regulator of access to technology could be addressed by the explicit linkage of proprietary rights to a new welfare axis comprised of development aspirations, human rights norms, and liberty considerations. To the extent social norms that develop around new technologies facilitate positive returns recognized by these complementary legal regimes, intellectual property rights that are in tension with these regimes will likely continue to lose moral sway, making the future of the TRIPS Agreement far less stable and its minimum obligations more costly to enforce. Moreover, gaps in how formal law and social norms regulate technology are not easily captured by the rigid prescriptions of treaty provisions, and thus the TRIPS Agreement is far less capable of serving the important role of shaping contemporary approaches to access to technology. As technology continues to reach deep into the private lives of citizens, and to affect the capacity and trajectory of national development in less-advanced economies, the design and construction of formal laws around which technology is produced, disseminated, and used will have greater import if they purposefully accommodate other legal orders whose norms resonate powerfully in advancing stylized visions of societal progress and human well-being.

Introduction

Technology is fundamental to human welfare and social advancement, perhaps more so today where technological engagement is indispensable for participation in political, cultural, and economic processes. At the level of the nation-state, sustainable access to technological inputs has profoundly shaped the direction of national economic growth, establishing the baseline for global competition and fueling intense conflict over the design and optimal blend of policies that best assure dynamic innovation without unduly burdening social welfare. The task nationally has been daunting for even the most advanced countries given deeply conflicting ideals about the constituent elements of social welfare, or the more elusive term 'progress.' The national difficulty with constructing a cohesive framework within which conditions for the production of and access to technology, including associated cultural goods, can flourish suggests that the long-term prospects at the multilateral level are quite dim. Nevertheless, legal rules that establish the policy context in which new technologies are designed, deployed, and accessed are already indelibly embedded into the global economic system through the multilateral intellectual property (IP) regime, established by the Agreement on Trade Related Aspects of Intellectual Property Rights (TRIPS Agreement).

The question whether the global IP regime can deliver welfare outcomes across countries of divergent institutional, economic, and technological capacities has elicited contentious international debates and, in some cases, dispute settlement by international tribunals. At one level, these battles reveal unresolved historical contests about the role of IP in economic development; at another, they suggest significant insecurity about the wisdom of private rights granted under national laws playing the role of technology regulator amid a complicated web of international norms and obligations. Consider, for example, that addressing global challenges such as climate change, global public health, and those reflected in the United Nation's ambitious Millennium Development Goals (MDGs), requires access to technology. Yet, in international fora where these issues are being addressed, the role of the IP system is either completely ignored (as in the case of the MDGs) or highly contentious (as with climate change and access to medicines). The sharp tension between the design of the multilateral IP rules and the need to facilitate optimal supplies of global public goods has been the subject of robust scholarly attention, but very little progress has occurred on the international policy front. The situation demands new approaches to constructing the relationship between law, technology, and society.

Toward a Coherent 'Welfare Axis'

Scholars have increasingly acknowledged that the IP regime sits within a broader political and normative framework. At least three major types of legal instruments mediate the relationship between law, technology, and social welfare imperatives: national constitutions, international economic arrangements, and the United Nations Charter on Human Rights. Each one manages the relationship between law and technology distinctly, with the advancement of human welfare ostensibly the only conceptual link between them. The three regimes are not independent, parallel means to a single end. Rather, each

represents a set of legal norms that interact and challenge the competing, and at times conflicting, premises upon which the global economic system rests, producing varying visions of the ideal relationship between law and technology. The globalization of IP through the TRIPS Agreement only adopts one of the distinct visions embodied in these regimes, namely the economic private rights imperative entrenched in trade policy. However, national constitutions and human rights regimes suggest that the economic narrative is incomplete and that an additional narrative of the relationship between law and technology is possible and necessary. This narrative views IP not only as a set of economic incentives to produce technology but also as a key player in the link between innovation and human welfare. The inclusion of IP in national constitutions, human rights instruments, and in a variety of economic agreements potentiates new social and political spaces in which economic, civil, and political rights can be reconciled within multiple multilateral frameworks. Across the various subject matter categories, the organizing norms of the IP system should be infected with global norms along a 'welfare axis' consisting of three main pillars: technology and human rights, technology and liberty, and technology and development.

Technology and Human Rights

Technology can be defined as innovation that pervades, alters, and transforms human potential and capabilities. Technology defines our human existence, both the limitations and the expressions. Technology encompasses both the process and outcome of applying knowledge to improve human existence. In the digital age, technology differs from the tool or product function it served when railroads revolutionized travel or the cotton gin transformed agriculture; instead, modern technology is both a means and an end in and of itself. Technology has become the principal medium of commerce, social interaction, communication, and political engagement. The United Nations recently declared Internet access to be a fundamental human right (UN Human Rights Council, 2011). The Internet, social media, and mobile phones have altered not only the means by which we communicate, but also redefined the format, frequency, and language of those communications. Many information technologies have risen to the level of essential facilities – key resources upon which social, political, and commercial activities depend (Marshall, 1999). One illustration is the role of social media as an instrument of political organization and change. Social media networks have been used to facilitate resistance to unpopular government policies, to mobilize networks of supporters of global social causes, and to galvanize uprisings and regime changes (Wolman, 2013). Technology has indisputably become an enabler of political and economic human rights and this reality must be reflected in the IP system.

Technology and Liberty

IP law frameworks are now the primary regulators of the private technologies that shape our public life and the public technologies that pervade our private spheres. The interaction of law and technology is increasingly mediated by exclusive rights granted to private actors, formally enforced by courts but also imposed through contractual arrangements or technology design choices that attempt further control on societal interaction. The growing intensity and pervasiveness of technology has engendered significant scrutiny and consternation about the appropriate form and content of legal rules affecting privacy, security, and freedom of expression. The political liberty interests of users are often undercut by the sheer breadth of control over the technical infrastructure that is essential to contemporary accounts of social welfare. From software code to social media, proprietors of information networks increasingly assume and exert control in ways less obvious but equally as troubling as government fiats. Constructive responses to the tension between liberty interests and technology regulation have been lacking in the IP policy space nationally (Cohen, 2012), and appear to be hobbling efforts unfolding within the international human rights framework (Land, 2012). In sum, the more exclusive rights of control we give IP owners in an age in which technology is a critical social good, the more likely there will be resistance to the unaccountable exercise of those rights in relation to other democratic interests.

Technology and Development

As a system of private rights in the products of human ingenuity, the IP system has long been at odds with global efforts to ensure economic growth and cultural development beyond the industrialized countries. While proscribing free riding, the rules of the TRIPS Agreement have had unintended consequences, most notably in framing a discourse about its negative effect on fundamental human needs. Technology is ubiquitous, yet access to technology is a mirage for the vast majority of the world's population. Despite the rapid rate of technological change, most global citizens live in poverty and many lack access to the most basic goods including water, health, and education. Access to technology may greatly enhance prospects for development. From stem cell cloning to mobile banking in rural Kenya, technology holds significant promise to extend and enrich human life, but only if the competing legal regimes can cohere meaningfully at the national and international levels.

These three organizing principles – human rights, liberty, and development – form an axis around which a new approach to global IP may be organized, in turn, catalyzing new approaches and attitudes toward pressing global challenges. This requires significant effort to transform the unyielding economic narrative in which the TRIPS Agreement is currently mired. To understand the incompleteness of the TRIPS Agreement as a comprehensive regulator of technology, the structural relationship between law and technology as mediated by the IP regime deserves brief attention in consideration of the welfare axis just articulated.

Global Economic Considerations, the TRIPS Agreement, and Domestic Welfare in the Design of IP Rules

The ideals that animate the terms and conditions of access to technology on a global scale are shaped by three legal regimes: IP, trade, and competition. Of the three, global IP rules have

been at the center of serious and protracted normative contests between countries, industries, and consumers over what the legal regulation of knowledge goods should accomplish and what values should inform the content of the governing rules. Between countries, these battles have remained stubbornly resistant to resolution, and instead have spread across diverse international fora and policy contexts (Helfer, 2004). The question of creating and managing global conditions that support technology development and use is further compounded by uncertainty over which structures and processes can best manage the confluence of social, political, economic, and institutional factors that shape conceptions of the role of technology in competing versions of the public good.

The legal rules countries adopt with respect to ownership, trade, and competition in technological goods are required to reflect the robust obligations of the TRIPS Agreement. The TRIPS Agreement, signed in 1994, established mandatory minimum standards of protection in all major categories of IP for all 158 member countries of the World Trade Organization (WTO). Most significantly, these obligations include extending IP rights on terms compatible with the principles of national treatment and most-favored nation status. The Agreement represented a significant upgrade from prior multilateral systems in terms of its comprehensive scope, the level of protection required, and, for the first time, the ability to compel compliance on pain of trade sanctions through the WTO dispute settlement process.

Despite this apparent international harmonization, the policy rationales underlying IP, competition, and trade are designed singularly to advance domestic welfare priorities. Laws and regulatory frameworks attendant to each subject are justified by explicit reference to *national* considerations for producing optimal conditions for innovation and creativity. Thus, despite strong rhetoric and a canonical narrative about the *global* welfare gains of harmonized IP laws, the international coordination of IP and associated legal regimes regulating technology is best understood or rationalized as an effort to limit the disruptive effects that free riding on public goods may have on the productive activity, and thus competitive advantage, of major technology exporters. In short, global IP rules have the effect of channeling the future competitive potential of developing countries away from technology-intensive sectors by making access to technology prohibitively expensive. Terms of global competition and economic growth are thus indirectly set through the design of global IP rights (Reichman, 2009), diluting the positive consequences of free trade, or otherwise limiting them to the technology exporters alone. The results are obvious: a longer path to economic development for less-advanced economies and a greater potential for dependency on foreign supplies of technical inputs at very high cost.

Nevertheless, it is clear that every country obtains technology by *some* combination of free riding, innovation, and trade. The dominant method at any given point in history is a function of, among other things, factor endowments, the size and quality of the labor pool, educational opportunities, and the terms or costs of access to technology. For example, critics of the IP regime established by the TRIPS Agreement were quick to point out that historically the United States and other industrialized countries enjoyed relatively low-cost access to technology by appropriating the inputs of foreign creators. In the same vein, ancient European city-states deliberately targeted skilled artisans, craftsmen, and innovators to import their technologies into the realm. These so called 'passports' – inducements to introduce new technologies into domestic markets outside the inventor's country – remain a justification for global IP, although less convincing today than once was the case. The reality is that such inducements alone have proven simply to intensify the structural conditions of underdevelopment by simultaneously raising the costs of access to technology and the provision of basic global public goods such as education and public health. It should be no surprise that the relationship between the IP regime and the demand for technology has become highly contested both domestically and internationally, exacerbated by rapid technological changes in information and communication technologies that constantly challenge the competitive capacity of major industries.

Global Welfare Concerns Shape the Legal Context of the Production of New Knowledge

But the TRIPS Agreement embodies more than just economic considerations. Or at least there are strong claims that it ought to. First, it is not self-evident that the economic incentives embedded in the TRIPS Agreement act to encourage innovation in the modern information economy. Even in the mature economies of developed countries, both the *presence* and *absence* of IP rights have galvanized new forms and expressions of innovative activity in the modern radically reconfigured economic environment. In this environment, global firms maintain diverse business models, championing some traditional IP ownership rights while simultaneously seeking to limit or jettison such rights where they threaten or disrupt activities that have become the mainstay of ordinary life for citizens in a globally networked information economy. It is also an environment in which new intermediaries provide much-needed information access points for citizens but whose relationship to IP owners and consumers is uneasy – especially with respect to liability for IP infringement. These new challenges, actors, kinds of economic behavior, and terms of sociopolitical engagement, all mediated by new technologies, point to innovation expressed around legal, cultural, and ethical considerations that demand a new construction of the TRIPS Agreement to accommodate values beyond its narrow economic logic.

Second, at an international level, the burden of legal rules that require compliance upon pain of trade sanctions has heightened social and political anxiety over the poverty-related challenges endured by the vast majority of the world's population. This constant anxiety has generated resistance to both the trade and IP regimes, destabilizing the normative assumptions of the public welfare vision around which (at least the domestic) IP rules have historically been organized. Although skepticism of strong IP rights has long been part of the multilateral IP domain, it has now become a fixture within the developed countries. Consumers everywhere have become the face and voice of a platform previously occupied solely by the technology-importing developing countries. The difficult

struggles over legal and technological controls on information flows resonate deeply in the native allegiance to personal liberty that occupies such a central role in Western democracies (Cohen, 2012). The collective impulse to reject incursions on personal liberty has converged in powerful ways: developing countries and their citizens, frustrated by their inability to enjoy the development path characterized by low-cost access to technology historically enjoyed by many developed countries have formed coalitions championing 'access to knowledge' and 'access to health' that serve as filters for assessing the welfare impact of global IP rules (Kapczynski, 2008).

As a result of these trends, the role of technology in global economic relations has become highly fractious, with no clear winners in the fight over the substantive legal norms that undergird international IP protection. The highly celebrated dispute settlement process of the TRIPS Agreement has had more symbolic effect than real; it has been less utilized (perhaps appropriately) against developing countries than originally expected, enforcement activities appear to be centered more on legislative action than on practical initiatives, and compliance with decisions has been suboptimal, particularly by the U.S. (Bird and Brown, 2012). Moreover, nationally, reform efforts and court decisions in leading technology-exporting countries suggest that the IP pendulum currently is not wholly aligned with the maximalist IP agenda of the domestic trade agencies. And among ordinary citizens, politically organized and technologically deployed social resistance to renewed efforts to increase the rights of IP owners has become part of the welfare motif in these same developed countries.

Human Welfare, Pervasive Technologies, and the Need for Legal Coherence

The ways in which technology is intimately integrated into every aspect of human life, from the most public to the most private spaces, mediating social, economic, and political interactions, have complicated the binary relationship between IP and access to technology. The ubiquity of technological choices directed at facilitating cultural interchange, political dialogue, and social expression has made it both doctrinally difficult and politically complex to simply view IP as a set of sacrosanct private rights insulated from the claims of other normative legal orders. The greatest challenges to the governance of knowledge goods and associated technological platforms stem *precisely* from the constraints that inhere in the role of the IP regime in facilitating effective and sustainable access to knowledge and the goods that embody it. For example, the tension between human welfare and IP at a global level has been particularly problematic because of the absence of a distinctive theory for global welfare outside the free trade context (Okediji, 1999). The advent of the TRIPS Agreement has broadened the responsibility for IP to address social and human welfare needs on global terms that have yet to be developed. A minimum function of the global IP regime should be to facilitate coherence among parallel legal regimes affected by the impact of technology – or the lack thereof – on the worldwide human welfare calculus.

The Complexity of Law and Technology Interactions

The lack of coherence among technology-dependent legal regimes stems partly from attempts to fit extremely complex interactions within simplistic, narrow models of behavior and interaction. Global IP policy should more accurately reflect the myriad ways that law and technology interact. These interactions are complex, reflecting both planned and unintended consequences and defining the organization, values, and possibilities of societies. Further, the interaction is bidirectional; technology influences the form and content of law and law influences the content and direction of technological progress. 'Law' includes formal, public codes, statutes, and regulations; private limitations imposed by technological architecture, contracts, and the market; and informal, public limitations imposed by social behaviors and norms. 'Technology' in this sense is defined as applied science or tools and techniques, as differentiated from 'basic' science, defined as fundamental research not designed to lead to a specific industrial application (Moses, 2007). Moreover in a broad sense, law and regulation are themselves a form of technology; they are the technology of civil ordering, a means of controlling inputs and outputs. So embedded is the notion of law as technology, and so intertwined are the functions, that policymakers often adopt the vocabulary of technology, seen in such references as 'policy tools' or 'regulatory toolkits.'

Since the explosion of the Internet, there has been a consensus among experts that technology design and use also function as a form of private law; the existing formal legal frameworks allow private technology owners and developers enormous latitude to shape the direction and form of technological progress, define conditions of access, and influence the architecture of social interaction and everyday life. For example, Apple smart phones running the operating software iOS are designed to access only Apple-approved content and certain cellular providers' networks. These limitations on use and access are built into the software code of the device; circumvention can only be achieved through a process known as 'jailbreaking,' a widely practiced method of unlocking the code limitations of somewhat dubious legality.

The widespread practice of jailbreaking despite its inconsistency with formal law illustrates the power of another form of 'law' – social norms. Social behaviors and norms exist in a more flexible and responsive framework than formal law, and are accordingly more rapidly molded and altered by technology. For example, the practice of jailbreaking phones arose in response to norms of sharing, personalization of content, and nondiscrimination on the basis of platform or type of device. Many online communities also self-regulate according to specific community norms; the online community Reddit, for example, is regulated by users who control the promotion of posts, stories, and comments through 'downvotes' and 'upvotes' in accordance with community norms that value novelty, inclusive dialogue, and brevity.

Of these three forms of law – formal law, the embedded private law of technology design and deployment, and social norms – social norms and private law are the most capable of quickly responding to technological change. Formal law, when it catches up, is either ratifying or dismantling an already existing relationship between social norms and technology,

suggesting that the TRIPS Agreement's focus on formal law undermines the powerful role of social norms and potentially leaves developing countries with fewer tools to respond to technological changes.

The Formal Law Lag

The TRIPS Agreement was negotiated and signed in the infancy of the information age: the full capacity of the Internet and mobile devices as economic, political, and cultural mediums of development and exchange had yet to be realized. Because the TRIPS Agreement was signed before the technological explosion and the development of a digital society, the legal regime it creates is obsolete and unresponsive to modern welfare concerns. The term 'cultural lag' describes this gap between the rate of change of material culture and nonmaterial culture (Ogburn, 1957). Material culture encompasses technological change and includes the physical equipment and the procedures for using and producing that equipment. Nonmaterial culture is comprised of moral, ethical, religious, and philosophical belief systems and values. Especially during rapid technological change, a culture lag can leave the nonmaterial culture without appropriate ethical tools by which to evaluate the design, use, and effects of technology.

There are several reasons that ethical tools lag behind technological development. Modern technological development occurs in insular and highly competitive communities (Marshall, 1999). In contrast to the idealized 'basic science' research community focused on publication and rapid dissemination of knowledge, IP regimes vital to technology firms place a premium on nondisclosure (Rai, 1999). Additionally, technological advances occur within tightly focused and controlled corporate structures largely isolated from public debate and disclosure over the technology being developed (Marshall, 1999).

Moreover, cultural lag is not purely linear, and different elements of material culture do not adapt and evolve at the same rate. Social norms and behaviors are more flexible and responsive than the more formal bodies responsible for public legal change, and are accordingly more rapidly molded and altered by technology than formal law. The resulting dissonance between formal law and social norms leads to a further 'law lag' within nonmaterial culture, where socially acceptable behavior or technology use is not reflected in the existing structure of formal law (Larsson, 2012). This lag is more pronounced today because of the rate of technological change and the comprehensive, global scope of communication made possible by the Internet and social media; social norms are globally consolidated and stabilized in ways that formal law simply cannot recreate and, instead, often seeks to delegitimize in the IP context.

Because of the flexibility and responsiveness of the social norm framework, social norms increasingly play the role of arbiter between technology and end users. Social norms do not pervade formal law as quickly as they pervade technology; technology is more responsive than formal law. By way of illustration, one view of the Google Books project to digitize and allow in-text searching of millions of books arguably is premised upon consumer expectations about the transformative nature of the Internet and the added value of digitized libraries. A 2013 lower court ruling holding that the scanning project fell within the 'fair use' exception in the United States copyright law could be framed as merely a formal confirmation of the already existing relationship between digitization technologies and experienced social norms. If an appeal by copyright owners is successful, it would begin a process to reinstate the explicit hierarchical order of property rights over decisions about how technology can be used and what the terms of such use might be.

The disconnect between the strong IP rights endorsed by the TRIPS Agreement and social norms is aptly demonstrated in the public debate and demonstrations that ultimately led to the defeat of the Stop Online Piracy Act (SOPA) and the Protect IP Act (PIPA) in the United States. Shaped by the ease of reproduction, variation, and distribution on the Internet, social norms of file sharing or file format shifting are seen as legitimate, while copyright law still defines those uses as infringing, contributing to a growing public perception of copyright enforcement as illegitimate. SOPA and PIPA, backed by copyright owner groups, sought to strengthen copyright enforcement by imposing affirmative requirements and liability on Internet intermediaries, such as service providers, search engines, and economic services like PayPal to identify and remove content that infringed copyrights. In response, more than 115 000 Web sites, including Wikipedia, Reddit, and Google 'blacked out' their home pages on 18 January 2012 to illustrate the potential effect of the proposals. As a result, an estimated 10 million people signed a petition against SOPA/PIPA, more than 8 million attempted phone calls, and 4 million e-mails were sent to Congress (Herman, 2012). This digital dissidence is remarkable not only because of its scope and impact, but also because of the abject failure of lawmakers to recognize the limits of IP laws in relation to social expectations of access to technology. The failure of formal lawmaking institutions to recognize how fundamentally out of touch existing IP frameworks are with new ideals of progress and the architecture of Internet technology remains one of the strong challenges to incorporating welfare concerns into interpretations of the TRIPS Agreement. Instead, as the law lag widens, the TRIPS Agreement remains a precedent for shifting regulatory authority away from public debate and formal legal bodies and toward private owner-mediated restrictions.

Reorienting IP Frameworks

Champions of the strong IP rights captured in the TRIPS Agreement reference the canonical bargains of IP rights as justification for the attendant negative externalities; IP rights are supposed to spur the creation of new products, knowledge, or creative works in exchange for legal protections. These bargains find theoretical backing in a narrative conceptualizing technology as a beneficial, autonomous force (Feng, 2000). This narrative also assigns value to certain exploitations and forms of technology, primarily widespread commercialization. However, the technology-centric narrative of TRIPS is not inescapable or necessary to spur innovation.

First, the conception of technology as value-neutral is neither accurate nor obligatory for a functioning, strong IP

framework. IP owners impose a form of private law by building limitations and controls into the design or architecture of technology. The value-driven aspects of technology are most obvious in software code. As Lawrence Lessig cogently explained, software code and the architecture of the Internet is a form of law and regulation (1999). Lessig's 'law of the code' is illustrated in content filtering software used to identify online content that infringes copyrights.

Second, the TRIPS Agreement embraces a narrow view of IP that assigns significance and recognition only to forms and uses of technology consistent with the developed world's definition of innovation and progress. However, it is increasingly clear that the categories and values we have chosen to recognize and elevate in the economic discourse are not ineluctable. As critical IP scholars have studiously argued, creativity in less-developed economies exists in some abundance. Forms of knowledge anchored in values distinctive to cultural institutions do flourish and are, ironically, misappropriated by 'innovators' from developed countries who exploit underinclusive IP frameworks. The axis around which contemporary IP relations revolve will unavoidably create a conflict between the protection that privileges innovation pathways unique to developed countries and the forms that creativity and innovation take in the developing world. The World Intellectual Property Organization (WIPO) Intergovernmental Committee for Genetic Resources, Traditional Knowledge and Folklore has been working on an international instrument designed to protect knowledge categories and resources traditionally excluded from IP frameworks. This is a vivid example of how new legal spaces for technology regulated through IP can be constructed. Within this WIPO process, the main proposal is for an international instrument to require patent or IP applicants to disclose sources of genetic resources and associated traditional knowledge where these have been accessed and used in the innovation process. A few developed countries are highly resistant to this proposal, sticking firmly to a conception of private rights and the patent system as the principal object of the human welfare calculus. As many of the developing countries have emphasized, however, the two knowledge systems are not irreconcilable within a broader framework of international law.

The Private Law of Technology

It is certainly improbable and even unfair to hold IP alone responsible for the fulfillment of human welfare aspirations, but it is also unwise to have IP resist or constrain the potential of other regimes directed at that end. With few exceptions, the TRIPS Agreement requires that formal legal limitations on technology be divorced from liberty and human rights policy considerations. As framed in the popular narrative, the TRIPS Agreement is indifferent to the evaluation or regulation of the ethical or socially responsible design, use, and distribution of the inventions in question, including essential inventions like genetically modified agricultural products, human genetic sequences, and information technologies. The inability of governmental entities to engage in policy consideration has placed technology owners in a position to fashion private law. Though framed as private rights, in reality, IP ownership is increasingly a right to govern by shaping the public space and exerting control over the deeply intimate choices of citizens.

IP owners fix the terms and conditions of access to technology in two main ways: by embedding access limitations within technology design and by setting the terms of deployment and distribution of essential technologies. The collective effect of this private law is a transition to a permission culture. Historically, innovation culture was postulated on an idea of 'free' culture – not as in 'no cost,' but rather as in free speech and free expression (Lessig, 2004). The opposite of free culture is a 'permission culture,' or a culture in which subsequent creators and inventors must seek permission in order to invent or create. This permission culture shift is driven not by public law or governmental regulation, but rather by the imposition of private controls in the regulatory spaces left open by gaps in formal regulation and by the expansion of IP protections without concurrent expansion of limitations. The permission culture of the private law of technology is not reflective of the interests of the majority of citizens, nor ultimately of the long-term economic interests of the private developer.

The shift to a permission culture controlled by private owners is of some concern because of the impact on essential liberty interests. New models of copyright enforcement require intermediaries, such as Internet service providers and search engines, to actively police for copyright infringement to escape liability (Graber, 2010). Many intermediaries have turned to automated content filtering technologies to police for likely infringement. These automated filtering technologies cannot cope with the inexact standards of the formal copyright law on the books, such as the many uses that fall within the 'fair use' exceptions to copyright infringement. Instead, the technology is overinclusive, acting upon and identifying a broader category of 'infringement' than identified in formal copyright law. In this way, the design or architecture of the software program, usually controlled by a private company, imposes constraints and grants rights different than the law on the books. The result is private, inconsistent, and often invisible intrusions upon the liberty interests of ordinary users fully sanctioned by both national laws and arguably mandated by the TRIPS Agreement.

The consequences of the shift to a permission culture reverberate in even the most fundamental areas of human rights, particularly health-care access. In the biotechnology field, the concentration of decision-making power in the hands of private owners can limit access to key treatments and diagnostics and inhibit future research and development. The patents at issue in the landmark U.S. Supreme Court case *Association for Molecular Pathology v. Myriad Genetics* covered genetic sequences and diagnostic tests associated with heightened risks of breast and ovarian cancer. Patents on these types of diagnostic tests are common, but many owners, recognizing the health and research implications, widely license the technology used in diagnostics. Myriad Genetics departed from this trend by refusing to license their diagnostic tests to other laboratories. This refusal to license allowed Myriad to acquire a monopoly, with all of the attendant consequences; tests were much more expensive, only covered by certain insurances, and limited to the most common mutations (excluding mutations more common in minorities). The American Civil Liberties Union challenged Myriad's patents on both patentability grounds and as violative of the First Amendment's guarantee of

free speech on behalf of researchers, genetic counselors, cancer survivors, breast cancer and women's health groups, and scientific associations. Although the Supreme Court held isolated genetic sequences to be unpatentable, patents on synthetic genetic sequences and diagnostic tests using those genetic sequences were sustained. Effectively, even after the decision, by virtue of owning the IP rights to the purified genetic sequences, Myriad is able to define the conditions of access to key health technology by imposing contractual conditions and other limits on the distribution of the test. Moreover, arguably the most valuable IP Myriad now has is its huge database of trade secret mutation information accumulated from all the years of performing the test, a database that will only be accessible, if at all, on the terms established by Myriad. In sum, IP rights engender resort to legal tools that foreclose public policy from influencing technology regulation, and these tools are beyond the purview of the TRIPS Agreement. Yet, as a form of regulation, the public welfare implications of these tools must be part of the social bargain inherent in the global IP regime.

The global IP system has long eschewed normative influences that might dilute its traditional emphasis on control and rent accumulation. The rapid evolution of information communication technologies has galvanized a much more sophisticated and growing public understanding of the extent to which the enjoyment of cultural goods and the exercise of political and social freedoms can be circumscribed by the exercise of IP rights. Put simply, the ubiquity of technology in the everyday lives of consumers strains the purely economic logic of the IP welfare calculus. This dissonance between how widely technology affects the exercise of political and social interests and the insistence on ever-increasing IP rights is largely behind contemporary cultural hostility to IP as the main policy instrument for regulating access to new knowledge goods and the technological platforms that ensure their proliferation. This hostility – both national and global – has also made policy discussions about the role of IP in promoting social welfare intractable and legal solutions politically unfeasible. To the extent IP rights justify the exercise of private power over all kinds of interactions with technology, it is unlikely to attract the legitimacy necessary to support the expansion of IP rights or improve prospects for better enforcement. The design and orientation of IP laws thus must be more accommodating of the values that define contemporary visions of human welfare as reflected in other legal regimes, such as human rights, in which private human ingenuity, economic development opportunities, and liberty interests can be nurtured and coexist.

Conclusion

Technology is deeply embedded in the routine and extraordinary moments of social interaction, economic organization, and political engagement. It seems implausible that the global IP regime can be meaningfully responsible for ensuring the fullest possible welfare gains associated with new technologies for consumers worldwide. It must therefore benefit from the multiple multilateral frameworks that also regulate the role of technology in facilitating human well-being. The global IP regime needs a welfare axis; it can and must cohere with development aspirations, strengthen liberty interests, and serve human rights goals. Nothing less will assuage the demand for a socially accountable system for promoting the production of technology and advancing human capacity to improve the material conditions that make human flourishing possible. TRIPS enforcement provisions notwithstanding, global consumers define what is lawful largely in reference to what is technologically possible, and not the other way round. Social practices thus inform and encourage technological production, use, and utility far more significantly in the information economy than exclusive economic incentives. Global IP policy must seek to narrow the gaps between formal law as established through the TRIPS Agreement, and informal social norms and technological controls that dictate consumer expectations of technology. In the end, such consumer expectations dictate the relationship between law and technology in ways much more powerful than the formal law on the books.

Law and Terrorism in the US and Beyond

Abstract

Development of a legal regime to counterterrorism is a modern phenomenon that is maturing in the twenty-first century. Prior to the 9/11 attacks, in most states terrorism was treated as criminal behavior, and the methods of deterring and sanctioning terrorism were drawn from the law enforcement experience. Counterterrorism law today includes distinct prevention elements, including investigations and detention authorities, discrete interrogation rules and practices, and the use of military force, among other elements. Counterterrorism law blends international and domestic laws, and includes human rights protections, special laws to govern armed conflicts, and several specific international treaties that respond to unique attributes of international terrorism.

Law and Terrorism in the United States and Beyond

Understanding the dynamics of terrorism and the law requires a clear picture of what terrorism is. Scholars have identified dozens of definitions of terrorism and a similar variety can be found in the laws of the United States and other nations and international bodies.

One definition that encompasses many of the widely accepted attributes of terrorism has been adopted by the US Department of State. It defines terrorism as "premeditated, politically motivated violence against noncombatant targets by subnational groups or clandestine agents, usually intended to influence an audience." The International Convention on the Suppression of the Financing of Terrorism, an international treaty adopted by the United Nations (UN) General Assembly in 1999 and ratified by over 130 countries, defines terrorism as "any…act intended to cause death or serious bodily injury to a civilian, or to any other person not taking an active part in hostilities in a situation of armed conflict when the purpose of such act, by its nature or context, is to intimidate a population, or to compel a government or an international organization to do or to abstain from doing an act." Finally, the US Department of Defense considers terrorism to be "the unlawful use, or threatened use, of force or violence against individuals or property to coerce and intimidate governments or societies, often to achieve political, religious, or ideological objectives."

Each of these definitions incorporates common aspects of terrorism. First, terrorism involves actual or threatened violent, premeditated actions. Second, the motivation behind terrorism – political, religious, or otherwise ideological – is distinct from ordinary crime. Third, terrorists use violence as a means of communication, getting the word out about their motivations and objectives. Thus, by using violent acts to convey political, religious, or ideological messages, terrorists seek an audience. That audience may be reached by the media coverage of the terrorist's issue, or through instilling fear in a population, which in turn pressures its government to recognize the terrorists' political agenda. Fourth, terrorists often seek to draw international attention to their causes.

Terrorism has ancient roots, where terrorists engaged in assassinations, fomented mass uprisings, or formed marauding bands to inflict harm on civilian populations. Terrorism evolved globally through changing tactics and the growing lethality and speed of weapons and other destructive instruments. In general, terrorists employed violence in discriminate and proportionate ways.

By the late 1960s, a new era of terrorism emerged. Terrorist groups began hostage taking for political purposes, often by hijacking airplanes. Three developments characterize the changing nature of terrorism during this time. First, terrorists began routinely to carry out attacks across international borders. For instance, it became common for airliners to be hijacked and diverted to another country for negotiations for the hostages' release. Second, the 'new terrorists' began targeting important political symbols, including the 1984 bombing of a hotel by Northern Ireland terrorists where British Prime Minister Margaret Thatcher was staying. Finally, terrorists learned how to take advantage of the media attention surrounding a terrorist event. For example, even though the attack by Palestinian terrorists during the 1972 Munich Summer Olympics ended in tactical failure, the worldwide media attention of the events drew attention to the Palestinian cause.

By the 1990s, the tendencies of terrorists to employ discriminate and proportionate violence in service of their goals was called into question. The number of incidents of international terrorism declined during the 1990s, but terrorists became more ruthless. The number of fatalities attributed to terrorist attacks grew dramatically during this time and into the 2000s. Experts only began to fully understand the nature of the threat of al-Qaeda and Islamic fundamentalist terrorism after the devastating attacks of 11 September 2001. Under the guise of religious rhetoric, Osama bin Laden declared war against America in 1996, calling on every Muslim to kill Americans. But in fact, al-Qaeda's objectives were political, seeking to expel the United States from Saudi Arabia and the Persian Gulf region. Al-Qaeda and other post-9/11 terrorist groups affiliated loosely with al-Qaeda depend on loose, network-based cells that operate with considerable autonomy, rather than a formal hierarchical arrangement. This model gives the group flexibility and resilience to counterterrorism strategies aimed at bringing down the organization.

Terrorist Motivations and Operations

To institute and carry out preventive measures to counteract terrorist threats, it is helpful to understand the motivations, and organization and tactics of modern terrorists and their organizations.

Motivations

Terrorists defy easy classification. They can be male or female, young or old, and from a wide variety of ethnic, religious, and socioeconomic groups. Examples of this can be seen in the increasing number of female suicide bombers in the Middle East, the high levels of education of many leaders of terrorist networks, and the existence of groups across the world, including the Tamil Tigers, narcoterrorists in Latin America, the Irish Republican Army (IRA), and the Euskadi Ta Askatasuna (ETA) (Basque Homeland and Freedom). Furthermore, modern terrorism trends indicate a necessary level of sophistication, resources, and training far beyond terrorist capabilities of the 1970s and 1980s.

While some terrorist acts are historically a way to draw attention to political or ideological agendas that have been ignored by the established order, other activities are more difficult to classify. Motivations can range from highly personalized worldviews to pure anarchism. The typology of terrorist motivations can be broken down into three categories: state sponsored, non-state sponsored, and individual.

Historically, evidence indicates that the primary motivations for state-sponsored terrorism include political, religious, or ideological reasons, or a combination of these factors. This support is usually evidenced through financial and/or military resources. Examples include the former Libyan government's involvement in the attack on Pan Am Flight 103, and its indirect support of the IRA and other European and Middle Eastern terrorist groups; North Korea's terrorist-style attacks across Asia; and Iran and Syria's support of Hezbollah.

Motivations driving non-state-sponsored terrorism vary widely, and include political and ideological issues, religious beliefs, organized crime, and issue-specific concerns such as social issues including racial or ethnic purity, abortion, or the environment.

Subcategories within political and ideological issues include separatist movements and cults or sects. Separatist movements such as the ETA, Tamil Tigers, and IRA, resort to terrorist activities in an attempt to gain independence for a specific geographic area or category of individuals. In contrast, cults often prescribe to a messianic or apocalyptic vision that offers the possibility of salvation if a particular lifestyle is adhered to. Since the 1980s, several cults have engaged in terrorist acts, including the Rajneeshi cult in the United States and the Aum Shinrikyo cult in Japan. The Rajneeshi cult utilized salmonella and attempted to poison the local water supply in Oregon in an attempt to achieve their political objectives by preventing residents from voting in a local election. The leader of the Aum Shinrikyo cult aspired to dominate Japan, and eventually the world, and ordered his followers to carry out a large-scale chemical attack in the Tokyo subway system in 1995.

Religious and political motivations are often intertwined and can be hard to differentiate. Al-Qaeda, Hamas, and Hezbollah all fall into this category. While the groups invoke religious rhetoric, they also compose political and social movements within various countries. The most prominent organized crime groups include narcoterrorists and the mafia. South America and the Middle East have seen an increase in narcoterrorism, which is used to intimidate or threaten the government and can be used to finance violent attacks while the Russian mafia has proven effective at utilizing terrorist methods by permeating the government, transportation, and construction sectors.

Individual motivations are notoriously hard to pinpoint, ranging from mental illness, to personal grudges, to ideological or religious beliefs. Arguably, the most famous example of individual terrorism is seen in Timothy McVeigh's bombing of the Alfred P. Murrah Federal Building in Oklahoma City in 1995. In the most deadly act of domestic terrorism by a US citizen, McVeigh detonated a truck packed with an agricultural fertilizer and highly explosive motor fuel in front of the federal building, killing 168 people and injuring over 850. Evidence revealed McVeigh held strong antigovernment and neofascist beliefs, likely motivating the attack.

Organization and Tactics

Modern terrorist groups have mostly abandoned the traditional hierarchical leadership structure in favor of a flat organizational structure. This new structure is composed of semi-independent cells that make operational decisions autonomously from a central leader. This decentralized structure also allows many terrorist organizations to have cells that each focus on a particular region.

Terrorist tactics have perpetually evolved in the last half-century. During the Cold War, state-sponsored terrorism was prevalent, with both the United States and Soviet Union sponsoring proxy groups to overthrow governments that one or the other opposed. By the 1970s, non-state-sponsored terrorism became more prominent. The groups, such as the Palestine Liberation Organization (PLO), used attacks to gain media attention and public awareness of their cause. The tactic of causing mass casualties was not popular until the 1990s, with the increased use of suicide bombers. Concerns for the evolution of terrorist tactics over the next decade include the possible use of nuclear, biological, or chemical weapons.

The Pertinent Law

The legal regime for countering terrorism is in its formative stages, although it is maturing. For a long time, nations responded to terrorism as criminal behavior subject to law enforcement methods and processes. Indeed, law enforcement approaches remain central to countering terrorism, although in the modern era the criminal paradigm has expanded to focus on preventing terrorism in addition to bringing those who engage in terrorist acts to justice. As a result, terrorist threats must be prevented, not just detected and prosecuted like ordinary crimes. Prevention requires investment in a relatively open-ended collection of intelligence, leading to the blending of traditional law enforcement and national security intelligence operations. Meanwhile, the most visible response to the

9/11 attacks was labeled a 'war on terror' by the Bush Administration and many others. The use of military force was joined with traditional law enforcement, national security intelligence collection, and various economic and soft-power approaches in what has become a multifaceted counterterrorism regime worldwide.

The expansion of counterterrorism beyond the criminal law model to intelligence collection (including various forms of electronic surveillance), financial tools, and the use of force has complicated and enriched counterterrorism law. Particularly in the years since the 9/11 attacks, international law and several states' domestic laws have expanded and taken new shape as counterterrorism law matures. The following sections provide an overview of the most significant components of the emerging international and domestic law regimes.

International Law

The UN Charter and Geneva Conventions provide the foundation for the regulation of the use of armed force against terrorists. UN Charter provisions outline the *jus ad bellum*, the legal bases for the right to wage war, and the Geneva Conventions and other international treaties, judicial decisions, and customary law provide for the *jus in bello*, the bounds of lawful conduct after war has begun. The Geneva Conventions aim to protect the victims of armed conflict and their terms define much of international humanitarian law (IHL). Originally largely only applicable to international armed conflicts – those between nation-state signatories to the Conventions – the adoption of Additional Protocols I and II in 1977 extended the basic Geneva principles to a broader range of conflicts, including noninternational armed conflicts – those not of an international character occurring in the territory of a state party to the Conventions. While these conflicts can reach terrorist activities, due to the nature of the violence and the involvement of nonstate actors, the Conventions and Protocols have failed to provide clear guidance for the rules that apply to terrorists. The United States has not ratified either protocol, but applies them to the extent that they constitute customary international law.

Human rights law (HRL) is a species of international law that traditionally applies to protect all parties, both combatants and civilians, in times of peace. However, most scholars and international tribunals agree that it also serves to complement IHL during armed conflict. Created through international custom as well as treaties and conventions such as the Universal Declaration of Human Rights and the International Covenant on Civil and Political Rights, HRL protects a person's fundamental human rights against both their own government and other international actors who may attempt to violate those rights. These rights include the right to life, liberty, and security of person and the prohibition of cruel, inhuman, and degrading treatment. HRL thus questions the lawfulness of targeted killings and indefinite detention of terrorists, among other preventive techniques employed by states. Consequently, for example, outside of combat, UN directives supplement HRL principles and support the need for imminence and necessity and a lack of available alternatives in order to use deadly force by military personnel or for preventive detention to be allowed in the face of arguments that it deprives the alleged terrorist's right to basic due process.

Since 1963 and the rise of modern terrorism, the international community has adopted 14 major legal instruments governing responses to terrorism, including conventions and protocols. Among other things, these conventions criminalize the use of civilian aircrafts and ships as weapons, define and prohibit the taking of hostages, regulate the possession and use of nuclear weapons, and allow universal jurisdiction over terrorist bombings. In 2006, the UN member states also adopted the Global Counter-Terrorism Strategy, the result of a General Assembly Resolution and a Plan of Action. This instrument attempts to coordinate efforts to address the conditions conducive to the spread of terrorism, determine both how to prevent and combat terrorism and how to build States' capacity to do so, and to create measures to recognize human rights and the rule of law as the fundamental basis for the fight against terrorism.

In addition to the UN Charter, IHL, HRL, and the various conventions, treaties, and international agreements focused on countering terrorism, the counterterrorism practices of nation states have begun to create customary international counterterrorism law. Customary law requires consistent and recurring action by states, along with a general recognition by states that the actions taken are required by international law. Finally, domestic courts, military tribunals, and international courts make counterterrorism law as a by-product of their decisions in individual cases. Although the courts typically intend narrow rulings directly affecting only the parties before them, the principles embodied in the courts' holdings often influence the development of counterterrorism law going forward.

Law Enforcement Approaches to Terrorism

General

The law enforcement approach to terrorism derives from the same deterrence theory that forms the basis of criminal law in general. The risk of arrest and punishment for violating the law deters individuals from violating that law in the future. Questions linger about how effective deterrence actually is against terrorists motivated by the righteousness of their cause. Nonetheless, there are several costs and benefits associated with law enforcement methods of combating terrorism.

When a terrorist is arrested and prosecuted, like Ramzi Yousef, the mastermind of the 1993 World Trade Center bombing, there is the direct benefit that he will not strike again. His arrest and prosecution in our courts also has indirect benefits. The United States gains a moral high ground by adjudicating alleged terrorists through the same judicial process as any ordinary crime. Moreover, the arrest of one terrorist may also have the effect of deterring others who might follow in his footsteps.

However, there are serious drawbacks to the criminal prosecution of terrorists. In addition to the uncertain deterrence effect, there is the risk that prosecution will provoke retaliation in the form of new terrorist attacks. Second, the public nature of criminal trials may serve as a pulpit for prominent terrorist suspects to draw further attention to the terrorist's cause. Third, criminal prosecutions are typically

successful only against the operatives who carried out the attack, not the leaders or masterminds of the terrorist organization since those individuals are usually far removed from the operations themselves.

Additionally, there are inherent difficulties in criminal prosecutions in general. The 'beyond a reasonable doubt' standard of guilt sets a very high burden of proof on prosecutors for any crime. Also, Constitutional protections require prosecutors to divulge to the defendant the evidence it plans to use, including the identity of intelligence sources, how the information was collected, and any evidence that may be favorable to the defense. Since many terrorism cases involve classified information, the government does not want to turn over such sensitive information to suspected terrorists. Two final challenges are that some foreign governments refuse to cooperate with US prosecutions where the death penalty could result, and that obtaining jurisdiction over suspects outside the United States is often legally and practically complicated by unclear laws and by the complex political and diplomatic considerations foreign nations must weigh when deciding whether to cooperate with a US terrorism prosecution.

Relevant US Statutes

The use of law enforcement in the United States to counter-terrorism is a modern phenomenon. This is partly explained by the fact that few acts of terrorism occurred on the US soil until the 1990s.

State-sponsored terrorism in the 1990s prompted the United States to impose sanctions and embargoes through the president's emergency powers, further enabled by legislation. The Trading with the Enemy Act, a World War I era law, criminalized certain commercial activities with enemies of the United States during wartime. It also granted the president, the power to restrict a range of other economic transactions with enemies and allies. The Act was amended between the world wars to grant the president its authorities whenever an emergency arose. During the 1970s, Congress reined in the president's executive discretion and created new procedures for exercising emergency powers by modernizing those authorities in the International Emergency Economic Powers Act (IEEPA). The IEEPA allows the president to impose economic sanctions during emergencies, which include 'any unusual and extraordinary threat' from outside the United States to the national security, foreign policy, or economy of the United States.

Current criminal laws on terrorism in the United States grew from these earlier sources of executive discretion to punish state sponsors of terrorism. Still, there is no single or uniform crime of 'being a terrorist' or 'engaging in terrorist activities.' Instead, terrorism crimes have developed over time, usually created in response to a terrorist attack, outlawing specific types of terrorist activities.

The decade between 1975 and 1985 saw a dramatic increase in terrorist violence directed against the United States with 2500 terrorist acts directed at Americans or US interests abroad. In 1986, the Omnibus Diplomatic Security and Antiterrorism Act was the nation's first effort at comprehensive terrorism legislation. For the first time, this Act made it a crime to harm Americans abroad. The focus of the act was on international terrorism, defined as violent acts, or acts dangerous to human life, intended to intimidate a civilian population. Additionally, the Act aimed to bolster security for diplomatic missions and to increase maritime security. It also authorized the offering of rewards for tips leading to the arrest of a suspected terrorist, and created a means to compensate victims of terrorism.

The 1993 World Trade Center attack, the 1995 bombing of a US training center in Riyadh, Saudi Arabia, and the 1995 bombing of the Oklahoma City federal building prompted Congressional action for more comprehensive legislation. The Antiterrorism and Effective Death Penalty Act of 1996 (AEDPA) considerably expanded the number and scope of federal crimes relating to terrorism, and increased the penalties for some existing offenses. Significantly, the AEDPA demonstrated that the United States would use legal mechanisms not only to prosecute terrorist acts after they occur, but also to anticipate and prevent terrorist acts.

In part, the AEDPA authorizes a variety of financial deterrents beyond traditional criminal law mechanisms, such as freezing and forfeiture of assets, prohibiting financial transactions with state supports of terrorism, and designating terrorist groups as foreign terrorist organizations (FTOs). Once a foreign group is designated as an FTO, its members are denied entry to the United States and the group's assets in the United States are frozen.

The most widely used component of the AEDPA criminalizes provision of 'material support' to FTOs. Particularly, after the attacks of 11 September, 2001, material support crimes became a central tool in combating terrorism. However, the anticipatory nature of regulating or proscribing acts of support leading up to a terrorist attack runs the risk of overly aggressive enforcement, punishing innocent acts such as expressive conduct, which may be constitutionally protected. The courts and Congress have revised and updated the material support provisions several times since 1996, following constitutional challenges to convictions under the Act. While the material support provision offers new broad authority, the spike in prosecutions following 9/11 returned to pre-9/11 numbers within 5 years of the attack.

Within weeks following the 9/11 terrorist attacks, the US Congress enacted the USA PATRIOT Act (United and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism). Lengthy and complex, the legislation was rushed through Congress with little debate and thus lacks clarity and leaves many issues unresolved. While heavily criticized, especially by civil liberties groups, the Patriot Act made only modest substantive additions to criminal laws. In fact, despite its 342 pages, the Act only contained a small number of controversial changes in the law, and those changes were subject to sunset provisions requiring subsequent legislation in order to remain in effect.

In brief, the Patriot Act enhanced the investigative tools considered necessary for the prevention of terrorism and updated the technological means of keeping track of terrorist activities. Where the Patriot Act did add to criminal laws, it did so by expanding and clarifying some of the definitions of terrorist activity, by adding variations to existing crimes, and by adding a few new crimes, including terrorist acts against mass transit, harboring terrorists, and acts of 'domestic terrorism.'

Detention, Interrogation, and Prosecution

Antiterrorism tactics should be distinguished from counterterrorism approaches. Antiterrorism actions are defensive measures used to reduce the vulnerability of individuals and property to terrorist acts. In contrast, counterterrorism is a broader term and encompasses actions taken directly against terrorist networks and other approaches that indirectly seek to render global and regional environments inhospitable to terrorist networks.

Detention

In times of armed conflict, the Geneva Conventions and IHL provide the legal guidelines applicable for detaining captured enemy combatants and for assuring their prisoner of war (POW) status. However, the evolution of modern warfare to so often include nonstate terrorists has complicated the definition of enemy belligerents, thus making it more difficult to definitively classify a detainee and assign him or her a lawful status and the rights that go along with it. With the passage of Additional Protocol I, POW protections were limited to enemy belligerents who openly carry arms and comply with the laws and customs of war, including the wearing of fixed insignia and organization of their force through a chain of command. These changes, in conjunction with the reduction in the number of international armed conflicts and rise in conflicts involving nonstate armed groups, have allowed states to individually re-create their obligations toward enemy combatants and the statuses of these individuals. For instance, the United States refuses to offer POW status to any enemy belligerent unless the person has been captured during an international armed conflict and satisfies the Geneva Convention requirements. Given that suspected terrorist groups seldom meet these measures, the United States has declared itself bound only to minimal HRLs in regards to detention and interrogation.

The United States allows for the detention of suspected terrorists and individuals who potentially possess knowledge of a terrorist activity, prior to the commission of any crime. This preventive detention has raised multiple Constitutional issues, in particular Fourth Amendment search and seizure and Fifth Amendment due process rights challenges, but the practice has been largely upheld in the interests of national security. Other countries' detention methods have received similar criticism. For example, the United Kingdom allows suspected terrorists to be detained without charge for up to 28 days, despite critiques that the practice violates the European Convention of Human Rights, which requires any suspect to receive prompt notice of the charges against them.

Aside from the states' domestic laws, international law also provides detainees with certain rights. Under the Vienna Convention on Consular Relations, an arrested foreigner has the right to have his government notified of the arrest. The Universal Declaration of Human Rights prohibits arbitrary arrest or detention. The protection against arbitrary detention is also included in the International Covenant on Civil and Political Rights, which also provides the detainee with the right to appear before a court to determine the lawfulness of the detention.

Interrogation

Reliance on torture to extract confessions is at least as old as ancient Greece. In intelligence investigations that take place in the aftermath of a terrorist attack, investigators do not know in advance what the detainee knows that may be of value. It has been very difficult to set legal rules to guide this uncertain quest for information. If there is a human tendency to extract information by any means necessary, it may be that abusive interrogation is the inevitable result of any legal regime short of an absolute ban on coercive interrogation. When the grotesque images of abhorrent abuses of detainees in US custody at the Abu Ghraib prison in Iraq became prime time news in 2004, and follow-on investigations revealed coercive interrogations conducted at the Guantanamo Bay detention facility by US agents during the same period, investigators learned that the then-existing international and domestic laws provided inadequate protections for detainees and insufficient guidance for interrogators in the conflict against nonstate terrorist suspects and insurgents. Debates raged over the practice of waterboarding and the hypothetical ticking bomb scenario. Political and moral issues punctuated discussions of law reform.

International law has long prohibited torture, as a fundamental principle of customary international law, through the Universal Declaration of Human Rights, the International Convention on Civil and Political Rights, the Geneva Conventions, and the UN Convention against Torture and Other Cruel, Inhuman or Degrading Treatment or Punishment (Convention against Torture). While most states have adopted the Convention against Torture, its critical terms – 'torture,' 'cruel, inhuman, and degrading treatment' – are not precisely defined. Despite the reform of US and some other states' domestic laws since 2005 codifying the international law bans on torture and cruel, inhuman, and degrading treatment, some government officials and interrogation practitioners continue to argue that enhanced interrogation techniques are warranted in light of the potential terrorist threats. (For a thorough discussion of these issues, *see* Torture: Legal Perspectives.)

Preventive Prosecution

Particularly after 9/11, US prosecutors utilized the technique of preventive charging against suspected terrorists. Preventive charging involves prosecutions based on actual law violations, although those violations are often far removed from the actual terrorist threats officials are attempting to disrupt. This technique is sometimes referred to as the 'Al Capone approach' (the Prohibition era gangster of Chicago was responsible for murder, extortion, and innumerable other violent crimes, but was ultimately arrested and convicted for tax evasion), or the 'spitting on the sidewalk approach,' in which a suspect is prosecuted for violating an innocuous municipal ordinance. At first blush, preventive prosecution appears harmless. However, following 9/11, the strategy spurred controversy over allegations that the so-called PENTBOM investigation (the Federal Bureau of Investigation's 'Pentagon/Twin Towers Bombing Investigation') was implemented primarily against noncitizens, particularly Middle Eastern men.

Despite risks of abuse, preventive prosecution still necessitates an actual violation of law. When the suspicious person has

not committed a crime, an alternative prevention strategy exists in the United States and some other states that allows for the detention of someone deemed to be a 'material witness' to a criminal prosecution in order to assure that he or she will be available to testify. Upon an assertion by the government, a person who could offer testimony material to the criminal prosecution of a terrorist can be detained indefinitely, so long as a supervising judge periodically affirms the detention is justified.

Rendition/Extraordinary Rendition

Rendition involves the surrender of a person from one nation to another nation that has requested that person, usually for criminal prosecution. However, the forms of rendition can range from informal, ad hoc occurrences to a formalized process such as an extradition treaty between two or more states. An extreme form of rendition – extraordinary rendition – involves situations in which, for example, the United States transfers detainees to foreign countries in circumstances in which it is likely that the individuals will face torture or cruel, inhuman, or degrading treatment.

While traditional informal rendition is characteristically regulated by legal agreements between states, extradition generally involves the use of treaties. Therefore, extradition typically requires 'dual criminality,' that is, the crimes for which the requesting state seeks extradition for prosecution must also be crimes in the state that would extradite the suspect. Thus, in a terrorism context, extradition treaties are often part of broader formalized agreements between nations to cooperate in criminalizing, investigating, and prosecuting suspected terrorists.

Extraordinary rendition was employed by the United States and perhaps other states after the 9/11 attacks, at least in part to avoid the domestic laws limiting interrogators. By implication, the international laws that forbid torture and cruel, inhuman, and degrading treatment – the Convention against Torture and the Geneva Conventions, among others – were violated in these instances. For the victims, it has been difficult to obtain remedies in the domestic courts of the state perpetrators of the renditions. Some have had limited success in obtaining redress from other government institutions, and in one case from an international court.

International Cooperation

Since the threat of terrorism does not respect national borders, countering terrorism requires a set of transnational responses. International cooperation to combat terrorism involves different states and international organizations working in a wide range of areas. Diplomatic efforts seek to develop and strengthen international prohibitions of terrorist acts and to encourage other nations to sign on to the international treaties against terrorism. Through economic cooperation, nations aim to eliminate financing capabilities of terrorist organizations and to use economic pressure to punish states or nongovernmental actors that support terrorists. Nonetheless, international cooperation against terrorism can be problematic.

First, states have different perspectives on terrorism. Seemingly unending disagreement on how to define terrorism and on whether terrorist acts can be justified in some circumstances makes international consensus difficult. Second, the types of terrorist threats each nation faces are different and can lead to diverging views on which responses are appropriate. Third, the capacity of each state to respond to terrorism can be wide ranging, further affecting its calculus of appropriate responses.

In spite of the challenges, between 1963 and 1999, 12 international conventions were established, each addressing different aspects of terrorism. Because of ongoing disagreements, these conventions tend to outlaw specific terrorist acts, rather than banning terrorism altogether. For instance, following a rash of airplane hijackings in the 1960s, an international treaty was established in 1970 outlawing the unlawful seizure of aircrafts. Additionally, the UN Security Council has passed numerous resolutions imposing sanctions on state sponsors of terrorism and restricting the financing of terrorism. Throughout the 1980s and 1990s, it imposed sanctions on states including Sudan, Iran, Iraq, and Libya. In 1999 and 2000, the Security Council also passed resolutions demanding that the Taliban regime in Afghanistan surrender Osama bin Laden to international authorities for prosecution. Following the 9/11 attacks, the Security Council passed Resolution 1373, "which called on all states to deny financial or other support for terrorist groups, to deny them safe haven, to share information and to assist other states in tracking down terrorists, to criminalize in their domestic laws both active and passive assistance for terrorists, and to enforce these laws." In response to the discovery of Dr Abdul Qadeer Khan's illicit nuclear supply network to North Korea, Iran, and Libya in 2004, the UN Security Council passed Resolution 1540, criminalizing the spread of weapons of mass destruction, especially to terrorist groups. Both Resolution 1373 and Resolution 1540 were adopted under Chapter VII of the UN Charter, which makes compliance with their provisions binding on all states.

These international treaties function to set standards for domestic laws. They commit nations to harmonize their national laws with the international standards those treaties establish. Through this mechanism, the international community can work toward creating global norms. In addition to pressuring signatories to adapt domestic laws to conform to treaties, international conventions help shape global public opinion, particularly by promoting an international consensus that terrorism is illegitimate.

Military Action in Response to Terrorism

Military force can be used in several ways in responding to terrorism. As a deterrent or preemptive measure, military forces can debilitate physical and economic assets in an attempt to incapacitate a terrorist group's ability to attack or make the costs of an attack too high. Military force is also used in self-defense, sometimes resulting in questions of violations of state sovereignty when the defending state crosses sovereign borders to attack a terrorist group. While the UN Charter, Article 51, permits states to use self-defense in response to an armed attack, if the government of the state to be attacked is not

supporting the terrorist group in some way, a law violation and international condemnation may follow.

The use of military force to combat terrorism has been employed with growing frequency. However, while the United States and other Western states can use conventional military operations to combat traditional state enemies, military operations are more difficult when fighting terrorists. The military often cannot differentiate between civilians and terrorists, due to the lack of insignia and traditional military chain of command, not to mention terrorists' failure to obey the laws and customs of armed conflict. Furthermore, the deterrent value of responding to terrorism with military force can be difficult to assess in instances where the terrorists have committed to death, such as in suicide attacks.

The United States is emerging from major military operations in Afghanistan and Iraq. While the intervention in Afghanistan was a direct response to the 9/11 attacks and initially seen as a self-defense measure undertaken eventually with the permission of the Afghan government and originally primarily composed of US Special Forces personnel, the intervention in Iraq was initiated on more questionable legal grounds – preempting a supposed threat of the use of weapons of mass destruction by the Iraqi government – and consisted of a full-scale military operation. The wars in Iraq and Afghanistan in general and the conflict against al-Qaeda in particular highlight several challenges when combating terrorist groups through the use of military force. First, while the United States and most western states have the capability to defeat conventional forces, terrorist forces rely on the techniques of asymmetric warfare – fighting from civilian areas and taking shelter in civilian dwellings, places of business and worship, for example – that is much more difficult to combat in operational terms. The asymmetric tactics also make it difficult for the defending state to comply with the laws of war, and may engender more distrust among the affected civilian population, or even stiffen the resolve of civilians caught in the cross fire to take up the terrorists' cause.

Throughout what has become a kind of shadow war by North Atlantic Treaty Organization (NATO), the United States, and its allies against al-Qaeda and its affiliates, military operations occur outside the traditional battlefields of Afghanistan and occur in several states in the Middle East/North Africa region. Because the nonstate terrorists often operate from within weak, failing, or sympathetic states, the use of force by states defending against ongoing threats of terrorist attacks often is criticized as violating territorial sovereignty and constituting offensive aggression. The defending states respond by maintaining that self-defense may lawfully be executed in the sovereign territory of another state where that state has proven itself unable or unwilling to remove the terrorist threat. As this unresolved legal quagmire continues, state practice may come to recognize the lawfulness of this exception to the integrity of sovereign borders.

The use of lethal force against designated individual terrorists, particularly by missiles delivered by unmanned aerial vehicles (UAVs), has proven especially controversial. The use of targeted killing through the use of UAVs has become particularly appealing due to the minimal threat of harm to US forces (the UAVs are piloted from remote locations, often far away from any battle space) and the possibility of fewer civilian casualties than through the use of conventional forces (because of the relative precision in targeting that may occur by employing powerful cameras and imagery technologies). Like the shadow war generally, targeted killing by UAVs outside traditional battlefields risks violating state sovereignty and arguably generates as much or more opposition to the defending state as existed before the drone strikes killed their targets.

Finally, counterinsurgency (COIN) operations became popular in Iraq and then Afghanistan for a time, undertaken by NATO, the United States, and allied forces in an attempt to garner support for military operations against terrorists and insurgents from local populations and curtail the spread of terrorist influences within the country. These operations, including fixing roads, building schools, and providing medical services, are primarily conducted by special operations forces and other military groups due to their high level of danger. COIN operations may be conducted in a sort of legal netherworld between war and peace. At times, the military forces may be involved in combat operations as part of COIN, while at other times they may be building local infrastructure, cultivating community support, or even negotiating with local fighters. The law of COIN is in its infancy, and it blends elements of the laws of war (IHL), HRL, customary international law, and the operational law of the engaged military forces. The military activities have drawn criticism from nongovernmental organizations and aid groups, who argue that they are being put at risk by the 'militarization' of aid and that neutrality is needed to successfully protect civilians.

Abstract

Anthropologists approach law as a form of normative ordering that includes rules and processes. The anthropology of law has evolved significantly from viewing law as a measure of civilization and savagery to understanding law as an emergent cultural feature and form of power. Contemporary anthropologists investigate law ethnographically, by looking at disputes in spaces that lack formal legal institutions and codified law, as well as in the institutional sites where law is produced. Plural legal orders, each invested with particular modes of authority, are seen as a feature of all societies. With the growth of globalization and transnational law, anthropology has extended its scope to explore the dialectical interaction between these multiscalar forms of law.

Anthropologists approach law from a comparative perspective and examine it in social context. 'Law' refers broadly to the rules, processes, and norms that regulate social life. Although there are frequently institutionalized systems for making decisions and enforcing them, legal anthropology does not restrict its attention to formal systems of courts or to the law of the nation-state. Anthropological approaches to law examine the legal ordering of villages, bands, and urban neighborhoods – places that usually lack specialized legal institutions and codified rules – as well as a wide range of institutional systems and technologies of law.

The anthropological study of law began from nineteenth-century evolutionary theories in which the form of law revealed the stage of social development. Twentieth-century legal anthropology examines processes of resolving disputes and maintaining social order on multiple scales. While interpretive approaches differ, law is understood as a form of power, invested with particular forms of authority. Recent scholarship has examined the relationship between law and culture, with special attention to the role of language. In examining law through its broader social and normative contexts, anthropologists have focused on the legal complexity produced by intersections among plural legal orders rooted in the community, the state, and international institutions and agents.

Historical Developments in the Anthropology of Law

The great nineteenth-century theorists of social evolution understood law as a measure of civilization and savagery. In *Ancient Law*, Sir Henry Maine (1861) theorized that with the transformation from kin-based to territorially based societies, law shifted its normative basis from status to contract. Similarly, sociological theorists such as Émile Durkheim and Marcel Mauss suggested that law emerged from an embedded form of repressive sanctions to an instrument arranged by specialized tribunals and functionaries that serves to maintain cooperation. These early theories identified law as a key facet of civilization, raising questions about the universality of law and the different forms it may take within distinct social and cultural contexts. As British social anthropologists pioneered the ethnographic method, they took up these questions and debated the very definition of law.

During the early twentieth century, two major schools of thought developed. One school followed from the work of Bronislaw Malinowski (1926), who defined law in functional terms, identifying it with a broad range of social processes that produce social conformity through social pressure and inducement. Through his fieldwork in the Trobriand Islands, Malinowski located law within the domain of everyday life, rather than the state or other institutions. He defined law in terms of the relationships of reciprocity that he argued were a fundamental mechanism for maintaining social control. With Malinowski's definition, every society has law. Critics of this view contend that defining law as social control is too broad and includes practices such as gossip, ostracism, and shaming that are not lawlike.

A second school took a more structural approach to define law in terms of institutions, requiring socially authoritative mechanisms for enforcing rules through the imposition of sanctions. Radcliffe-Brown pioneered this perspective, defining law as "social control through the systematic application of the force of politically organized society" (1933, p. 202). Under this definition, all societies have customs and sanctions, but not all societies have law. E.A. Hoebel defined law more broadly, but also within an institutional context, as "the legitimate use of physical coercion by a socially authorized agent" (1954, p. 26). In *The Cheyenne Way*, Hoebel and legal scholar Karl Llewellyn developed a case-method approach to look at 'trouble cases' (1941). This early collaboration demonstrated the importance of anthropological approaches for legal scholars and other social scientists. As progressive legal scholars associated with the legal realist school critiqued formalist or positivist jurisprudence – the then-dominant paradigm among legal scholars and practitioners – they turned to anthropologists to demonstrate the cultural effects of law. Critics of this view of law, however, argue that this rule-based perspective is based on Western conceptions of law (Comaroff and Roberts, 1981, pp. 6–7).

Between the 1930s and 1960s, anthropologists sought to describe the nature of rules of whole societies. For example, Isaac Schapera attempted to develop an entire casebook of

Tswana law based on his ethnographic research, while Leopold Pospisil sought to provide a more far-reaching universalistic definition of law based on his fieldwork with the Kapauku Papuans. Yet these scholars confronted the paradox that there were frequently discrepancies between these rules and everyday forms of behavior. Moreover, anthropologists debated the very nature of the comparative method?. While Max Gluckman argued that indigenous legal concepts processes could be translated into the terms of Western jurisprudence, Paul Bohannan countered that these terms could be understood only in reference to the total social and legal systems of which they were a part. This debate, which went to the heart of the definition of law and the nature of legal comparison, became increasingly sterile. By the 1970s, this debate was largely abandoned in favor of understanding law as a social process (see Moore, 1973; Nader, 1997).

Law and Dispute Processes

In the early 1970s, anthropologists turned to studying processes by which conflicts are handled and resolutions achieved (see Moore, 1978). Laura Nader and her students researched how litigants pursued disputes and how these disputes were resolved in a wide variety of societies (Nader and Todd, 1978). This approach used extended case study analysis and emphasized the perspective of litigants rather than judges. It broke dramatically with the earlier focus on rules and looked instead at the processes by which individuals pursued grievances. At the same time, it built on a tradition of analyzing extended case studies in the context of social relationships. For example, Max Gluckman argued that close-knit villages tended to have compromise settlement processes, while more loose-knit ones favored more adversarial processes (Gluckman, 1973). The focus on dispute processes remains a basic framework for the anthropology of law.

By the early 1980s, however, it became clear that a focus on the processes of resolving conflicts could not be separated from a consideration of rules and how they were formed. In their study of the Tswana, Comaroff and Roberts found that the meaning and relevance of rules are negotiated in disputes (1981, pp. 5–17). Arguments among disputants are framed by rules, but the content of rules is negotiated as disputes are argued and resolved (1981, p. 19). This more interactive understanding of rules and processes has proved valuable for examining the operation of law in communities as well as in more formal settings, such as courts. It led to an approach that conceptualized law as more deeply embedded within culture, as a system that was both constituted by and constructive of social meaning.

Law, Culture, and Language

The legal system of a society reflects its fundamental values and its normative order (Rosen, 1989). Geertz (1983) describes law as a form of 'local knowledge' that is 'a distinct way of imagining the real.' In developing an interpretive, comparative approach, Geertz argues that anthropological analyzes should approach law as a normative process of social representation. Law is not merely constitutive of social reality, but also reflects particular ideals of justice. To capture this dialectic, Geertz suggests that the comparative study of law should consist of the study of 'cultural translation.' In analyzing this process of translation, anthropologists have pointed out that law is essentially a language and that legal procedures are fundamentally linguistic.

Following a processual model of analyzing law, Sally Humphreys (1985) suggests that law can be studied as a form of discourse that is embedded in particular notions of power. Taking up this approach, scholars developed a focus on law and language that combines sociolinguistic analysis and law and society scholarship to look at the way that law creates meanings and exercises power through linguistic exchanges in courtrooms and other legal settings (Conley and O'Barr, 2005). This work provides a way to look at the detailed interactions that determine how the law exercises power. For example, many features of the kinds of talk that are persuasive in American courtrooms are more characteristic of male than female speakers, and of powerful rather than powerless speakers, so that male litigants in these courtrooms have an advantage (Conley and O'Barr, 2005). Analyzing the microdiscourses that take place in mediation centers, courtrooms, and other legal settings, scholars have applied insights drawn from linguistic anthropology, such as conversation analysis, to show how macrosociological relations of power are constituted through techniques such as controlling silences and suppressing arguments.

Legal language and institutions also offer avenues for resistance. In particular, the language of rights has proved a powerful framework for social justice movements, especially since the end of the Cold War. Rights talk has been central to labor movements, indigenous people's movements, the anti-apartheid movement in South Africa, and movements for women's rights, to name a few examples. Local groups around the world now draw on global conceptions of human rights for inspiration. Much contemporary social justice talk and activism take place within the domain of law. Anthropologists have questioned whether the proliferation of formal rights language offers a useful form of resistance in the diverse and complex struggles that individuals and groups are engaged in to contest culturally constituted inequalities in diverse regions of the world. Merry's (2006a) investigation of the Convention to End All Forms of Discrimination against Women focused on the ways that elites translate between the vernacular language of duties and responsibilities and the global language of human rights. Although human rights must be vernacularized to effectively change relationships of power within a given society, she argues, the language of human rights nevertheless "comes with a price. Human rights promote ideas of individual autonomy, quality, choice and secularism even when these ideas differ from prevailing cultural norms" (2006a, p. 4). This work has described the deeply embedded cultural and political conceptions within legal language as well as the limits of legal language as a form of social representation (Hastrup, 2003). As the language of law is deployed within different cultural milieus, anthropologists have attended to the ways that people wrestle with the legal categories through which they must make their claims.

Anthropologists have also drawn from linguistic anthropology to track the ways in which law serves as a particular ideology that is embedded within normative epistemologies. Elizabeth Mertz describes how the pedagogy of US law schools serves to socialize law students into a particular, 'culturally driven model of justice.' Students are systematically 'urged to pay attention more to abstract categories and legal (rather than social) contexts' that serve to cultivate the authority of textual analysis and legal form (2007, p. 5). Mertz shows while legal language and processes offer a creative system for handling disputes, they may also privilege particular cultural viewpoints over others. Similarly, Justin Richland (2008) describes how language ideologies often conflict within Hopi jurisprudence. While he too notes how legal language serves to socialize a particular population into the ideology of law, he also shows how these ideologies may be transformed over time through mutually constitutive interaction with divergent worldviews. Through close linguistic and interactional analysis within a Hopi courtroom, Richland examines the way in which Hopi judges and lawyers attempt to develop a Hopi form of jurisprudence based on 'tradition.' He suggests that Hopi law and ideas about tradition are constituted through a dialectical tension between Hopi and Anglo-American concepts of objectivity and forms of narrative.

Law and Power

The law also provides a rich vocabulary for describing and legitimating relationships of unequal power. It contributes in significant ways to the hegemony of a political system by engendering consent and fostering legitimacy for its exercise of power (see Nader, 1991). Since the 1980s, the anthropology of law has become concerned increasingly with the relationship between law and the exercise of power (see Starr and Collier, 1989). Inspired by Marxist and Foucauldian theories as well as the Critical Legal Studies Movement in law schools that argued that law reflects the interests of dominant groups rather than simply the logic of legal reasoning, anthropologists examined the way law supports relations of power in a wide range of social contexts (see Lazarus-Black and Hirsch, 1994). However, this research also demonstrated how law challenges dominant groups. It showed law to be a double-edged sword, expressing the rules and sanctioning authority of established political authorities and at the same time offering opportunities and justifications for resisting political authorities.

For example, social movements that call on civil rights, such as the US civil rights movement against racial discrimination in the 1950s and 1960s, challenge existing power hierarchies. Feminists have used the criminal law to challenge male privilege by demanding penal sanctions for those who use violence against women in intimate relationships. The discourse of human rights has been deployed by indigenous peoples, women, victims of war atrocities, prisoners of war, and many other groups to claim protection from state authorities. Thus, law usually reinforces existing power arrangements, but can provide an avenue of resistance through its institutions and the discourse of rights.

Attention to the way that legal forms and institutions exercise and legitimate power, while offering a mode of resistance, leads to concerns with the way that laws are produced and enforced as well as with the linguistic and social exchanges that take place in courtrooms, police stations, and lawyers' offices (e.g., Conley and O'Barr, 1990). Increasingly, anthropologists have examined the technologies and forms of law itself. Rosemary Coombe (1998) analyzes the regime of international property law to reveal the underlying conceptions of individualism and agency implicit within these laws. She documents how, as Canadian First Nations engage with the language of intellectual property laws to contest the 'cultural appropriation' of native knowledge and symbols, they also resist its underlying possessive individualism. Indigenous groups deploy a 'double-voiced rhetoric,' whereby "they empty tropes of a dominant language simultaneously engaging and subverting these metaphors through the character of the alternative claims they make into the voice of an authorial other" (1998, p. 242).

Another approach to understanding law and power integrates insights from Science and Technology Studies to examine the content, form, and agents involved in the production of legality as a technology and network. This approach does not focus directly on the relations of power that underlie law-making processes. Instead, it shows how technologies of law, in the form of doctrine, interpretive techniques, or dispute resolution tools, produce forms of knowledge that conceal more substantive, political issues. Both Bruno Latour (2010), in his study of the French Conseil d'État, and Annelise Riles (2001), in her study of Fijian activists negotiating human rights language for the United Nations Fourth World Conference on Women in 1995, seek to open up the 'black box' of law. This is Latour's term for complex techniques that scientists present in diagrams as taken for granted rather than present in detail. Latour and Riles both analyze the details of legal processes to show how technologies of lawmaking become tools to overcome political and epistemological limits. Whether studying the objectivity of judges or the use of 'bracketing' as a way to move past substantive disputes in the United Nations, each of these technologies produces knowledge that is translated into commonplace understandings. Similarly, Merry (2011) examines new tools of international governance, such as the use of quantitative indicators to measure qualitative categories such as 'the rule of law,' as technologies that transform political decisions into scientific, empirical knowledge (see also Davis et al., 2012).

Scholars have also looked to the way that law imposes new forms of power through constructing and transforming notions of space. Drawing on the work of cultural geographers, these studies recognize space as a key constituent of social life that plays an important role in the construction of social relationships and the formation of the political domain. Since law is the apparatus through which states define political territories, as well as their domestic and public spheres, it is a key form through which space is made (see Law and Geography). Benda-Beckmann et al. (2009) explore the relationship between competing spatial configurations of law within plural legal orders. By exploring the plural legal orders and their particular notions of space, they argue that "multiple legal constructions of space open up multiple arenas for the exercise of political authority, the localization of rights and

obligations, as well as the creation of social relationships and institutions that are characterized by different degrees of abstraction, different temporalities and moral connotations" (2009, p. 4).

Legal Consciousness and Identity

Anthropologists have investigated the relationship between law and power in the construction of personhood and subjectivity. Law constitutes social identities and understandings of social relationships through its regulations and through the spectacular as well as the mundane processes of arrest, trial, and mediation through which these regulations are enforced and failure to comply is punished. Even when laws do not impinge directly on social life, they exercise power by shaping individuals' legal consciousness. This refers to the way in which people see themselves defined by and within law, the rights they can assert, and their entitlement to seek legal remedies for grievances in studies of legal consciousness, anthropologists use disputes to investigate these matters. These studies approach disputing as "a contest over meanings in which the law provides one possible set of meanings. The process of disputing is one of quarreling over interpretations of social relationships and events" (Merry, 1990, p. 6). Studies of legal consciousness illuminate the way that everyday understandings of law become important factors in the development of 'community' and social relations. Merry's work on working-class, urban legal consciousness showed how law becomes a means for challenging hierarchies of power and asserting privacy in opposition to social conflicts or constraints engendered by other forms of informal ordering. Similarly, in a collaborative effort to investigate the role of law in three American towns, Carol Greenhouse et al. (1994) suggest that law is a social practice that constructs the meaning of 'community' by defining 'insiders' and 'outsiders.' Exploring the reasons for litigation within their three respective sites of study, the authors found that law was either interpreted as a sign of difference and 'outsider' status, or as a form of 'insider' status by those seeking to defend the 'community.' Hence, they use the disputing approach to demonstrate the important role that law plays in constituting notions of community.

More recent studies of legal consciousness by scholars in other disciplines explore how people perceive injustice, understand themselves as rights-bearing subjects, and develop their identity based on new rights. Ewick and Silbey (1998) describe the schemas, or positional stances, that individuals develop to understand their relationship to the law. Laura Beth-Nielsen's (2000) research examines the everyday attitudes and understandings of law as a way of dealing with sexual harassment. David Engel and Frank Munger (2003) analyze how the disability rights movement constructs identities around what it means to be disabled and when and why disabled people mobilize these rights. David Engel and Jaruwan Engel (2010) document a surprising shift in legal consciousness concerning personal injury cases in Thailand as ordinary people turn away from the law.

Anthropologists have also focused on the way in which legal ideologies constitute conceptions of subjectivity that shape identity claims and understandings of the self. Law participates in the construction of identity by soliciting specific expressions of difference. By constraining the types of claims that can be made, Collier et al. (1996) contend that the law sanctions particular types of identity making. Rather than recognizing all difference as socially produced, they suggest that legal mechanisms recognize only those claims that translate their identity into 'natural' categories. Thus, formal legal mechanisms do not recognize the types of difference that law itself has produced. This is a contradiction that anthropologists have documented as groups seek remedies for state and social discrimination by state courts. For example, James Clifford (1988) describes how the Mashpee struggled for recognition as a 'tribe' under the Non-Intercourse Act in the United States. In this case, the court became a site to adjudicate a group's collective sense of identity based on legal categories rather than the self-understanding of the community.

Land claims have proved a particularly important site for anthropologists to investigate the relationship between identity and law. Elizabeth Povinelli (2002) describes how aboriginal land claims in Australia require authentic indigenous subjects who are "called on to perform an authentic difference in exchange for the good feelings of the nation and the reparative legislation of the state" (2002, p. 6). Yet there is an inherent contradiction, a 'cunning of recognition,' in that as the state recognizes aboriginal people and difference more broadly, it defines what constitutes an appropriate form of difference. People and groups must therefore represent themselves through these categories in order to win recognition of their legal rights. This, the process of recognition, extends the reach of liberal legalism. Jan French's study of Brazil (2009) shows how recognized categories of indigenity alter the lived experiences of people who adopt legally recognized categories for identity, reshaping their social relationships and claims to land.

The intersections between law and identity are increasingly central issues in the anthropology of law. Law constrains and limits identity claims by granting or denying citizenship to people who travel across transnational boundaries. The complex relationship that ensues when the law seeks to erase past forms of identification and construct new relationships to the state via identity is the focus for Susan Coutin's (2000, 2003) and Barbara Yngvesson's (2010) works, but in different contexts. Coutin's research on Guatemalan and Salvadoran immigrants to the United States and Yngvesson's research on transnational adoption both explore the ways in which adoptees and immigrants must reconcile forms of identity no longer recognized by law. These authors show the power and authority of law as an epistemological regime that confers particular forms of 'truth' to individuals in the process of self-making. Not only does law define identity, as Yngvesson (2006) and Coutin (2000) and both together (Coutin and Yngvesson, 2008; Yngvesson and Coutin, 2008) demonstrate, but also, as borders shift, identities can change even as people remain in place. Tobias Kelly's (2004, 2006) analysis of residents of the West Bank in Palestine illustrates this phenomenon vividly. With the development of research on legal consciousness, the relationships among legal culture, legal consciousness, and legal identity are increasingly complicated and overlapping, requiring clear definitions of terms (Merry, 2012).

Legal Pluralism

In the contemporary world, societies typically have more than one legal system. Legal pluralism refers to situations of legal coexistence in a single social field (Merry, 1988). Initially described in colonial situations, in which the colonial power superimposed a European legal system over an existing indigenous system, legal pluralism is now understood as a fundamental characteristic of all legal systems. Early insights into legal pluralism within advanced capitalist states were drawn from Sally Falk Moore's (1978) description of semiautonomous social fields, domains of social life that are self-regulated but also subject to larger forms of regulation, such as commercial networks or criminal communities. Legal pluralism has since been used to understand the multiple layers of regulation developed out of both private and public forms of governance. For example, many institutions such as schools and corporations develop forms of private governance. Informal but rule-governed relationships are also characteristic of families, communities, and voluntary organizations, although there is considerable debate about whether such forms of normative ordering should be called law. The term 'interlegality' emphasizes the interactions among multiple legal orderings (De Sousa Santos, 1987).

Early descriptions of plural legal systems examined each in isolation, but more recent work emphasizes the way that plural systems shape one another. Typically, plural legal systems are shaped by differing relations of power. In colonial situations, the colonial authority often established one legal system for the subjugated and another for the colonial authorities (Moore, 1986; Merry, 2000). However, as anthropologists examine postcolonial and contemporary international forms of governance, they focus on interactions among legal systems and their impact on litigants and on each other. For example, Richard Wilson's study of the South African Truth and Reconciliation Commission argues that the plural legal systems in South Africa represent different forms of authority and approaches to dealing with past injuries. Taking a processual approach, he suggests that studies of legal pluralism should focus on the way that the state and other actors seek to legitimate legal orders within the broader context of state formation and resistance (Wilson, 2001).

Globalization increases legal pluralism in two ways. First, it fosters the circulation of legal forms and practices from one nation-state to another. Constitutions, codes, and legal institutions are commonly transplanted, much as they were during the earlier period of colonialism. These transplants introduce codes and procedures quite different from those of the receiving society, often with the intention of reform. Colonial transplants characteristically were phrased as furthering civilization, mid-twentieth-century transplants as modernizing institutions, and late twentieth-century ones as promoting democracy and the rule of law. Ugo Mattei and Laura Nader (2008) argue that in the post–Cold War era, the 'rule of law' has been promoted as a nonpolitical, nondistributive technology that lacks the institutional virtues of democracy promotion that were central to efforts of Third World development during the Cold War. As such, the export of rule of law, they argue, has been a proxy for privatization and neoliberalization.

The growing field of 'transitional justice,' which refers to the wide array of processes and formal mechanisms that states establish to deal with past mass human rights violations, constitutes another form of legal pluralism. Transitional justice processes seek to reconstitute the state and restore the rule of law as a necessary precondition for democratic transition. Over the last two decades, several formalized approaches to transitional justice have been created. These approaches include criminal prosecutions, truth commissions, reparations, lustration, and memorialization. In theory, these approaches are complementary. States may choose to apply multiple approaches at one time, or may use several approaches successively. These approaches are used in a wide variety of political environments ranging from military dictatorships to ethnic civil wars. The field of transitional justice has engendered a large cadre of professionals who do this work around the world.

Considerable anthropological research in the field of human rights and transitional justice focuses on the way these global justice systems operate in practice. Anthropologists tend to link local ethnographic research with examinations of the global institutions promoting human rights and international justice. Mark Goodale (2009) explores the history of anthropology's engagement with human rights, while Hinton and O'Neill (2009) offer a series of anthropological perspectives on the way that local communities in many parts of the world experience transitional justice in response to genocide. Harri Englund's (2006) study of the way that human rights are understood and used in Malawi provides valuable insights into the difficulties of translating and implementing human rights in situations of autocracy and political opposition. Kimberly Theidon (2012) examines the workings of the Peruvian Truth and Reconciliation Commission from the perspective of highland Peruvians who suffered from the violence of the period of struggles between the Shining Path and government soldiers. Kamari Clarke's (2009) analysis of the International Criminal Court takes a local as well as a global perspective on the kinds of justice that this new international regime provides, suggesting that its local practice differs from its global aspirations. Ethnographic studies of the meanings of human rights in local communities show that they are one discourse among many, and often not the dominant one. For example, Daniel Goldstein (2012) shows how concerns about security take precedence over human rights in a poor urban neighborhood in Bolivia.

Secondly, globalization increases legal pluralism by constructing a global legal order that exists outside state law. As international law and international organizations expand, legal pluralism provides a valuable analytical framework for understanding this broadening range of legal forms. The human rights system, made up of rules and sanctioning systems embedded in international institutions such as the United Nations, is a central facet of the new global legal order (*see* Human Rights, Anthropology of). Although the human rights system is a multilateral treaty regime built on a system of sovereign states, it is redefining the nature of state sovereignty itself. Pressure for compliance with human rights by states and transnational nongovernmental organizations is circumscribing state sovereignty to some extent. At the same time,

domestic actors such as indigenous peoples seek to constrain state sovereignty as they make claims for legal and political autonomy using international principles of self-determination and rights to protection of culture.

Anthropological research explores the processes by which human rights categories are constructed. For example, Tobias Kelly (2011) examines a series of settings in which legal institutions determine whether or not a person has been tortured as a way of understanding what torture means. He shows that the category is constructed through social processes rather than through a preexisting definition. Richard Wilson (2011) takes a similar approach in his analysis of the way in which international criminal tribunals generate historical accounts of war crimes and genocide by looking closely at the operation of the International Criminal Court.

Another form of transnational law that legal pluralism has been used to understand is the expanding field of international commercial law, which includes a wide range of mechanisms from formal treaties to informal law based on nonbinding agreements to corporate self-governance. Finally, the creation of new regional legal entities such as the European Union is also exploding the autonomy of local legal orders (Darian-Smith, 1999).

As anthropologists turn their attention to these transnational legal orders, they have expanded and further developed ethnographic methods to analyze intersecting legal orders on multiple scales through 'multisited' ethnography (Marcus, 1995; Merry, 2006b). Multisited ethnography, including sites that are vertically connected local and global spaces, enables anthropologists to explore the many ways in which both separate legal orders and the 'local' and 'global' are not opposing entities, but rather mutually constitutive social fields.

Conclusion

The anthropology of law changed dramatically over the twentieth century. While earlier theories saw law as a structural feature of a whole society and used it to classify societies, more recent anthropological studies examine dispute processing, the linguistic and cultural features of legal settings that shape the way power is exercised, and the extent to which legal categories and concepts are embedded in individual consciousness and local culture. At the same time, the notion of culture as an integrated, homogeneous, and consensual system has been replaced by models of law in society that focus on the multiple and contradictory nature of rules and procedures. Contests among these systems of power and symbolism account for social change. Some of the competing frameworks are the product of alternative systems of legal regulation developed through colonialism or globalization. Contemporary legal anthropology views law as the product of contestation about meanings and identities in social fields constituted by multiple legalities. It examines the way that law exercises power and sees this process as mediated by legal procedures, linguistic forms and exchanges, and cultural practices that shape legal settings and provide individuals with access to these settings.

Law as an Instrument of Social Change

Abstract

To review law as an instrument of social change, one first has to address what one means by 'law' and by 'social change.' We can then examine the mechanisms through which law changes society. This article begins with methodological and definitional issues in studying law as an instrument of social change. It then reviews empirical findings about the mechanisms through which law changes society, focusing in particular on the debate about rights litigation as a social change strategy, the ways organizations respond to legal institutions and implement law, and the relationship between law and social movements.

Introduction

At least since *Brown v. Board of Education* ordered southern states in the United States to desegregate their schools, whether and how law operates as an instrument of social change has attracted intense scrutiny. This inquiry's deceptively simple formulation masks significant complexity in the concepts of law, social change, and the relationship between them. Because different empirical and epistemological traditions approach these concepts quite differently, this variation broadens the understanding of law and social change and fuels a rich and expanding literature in the social sciences. This brief article cannot address all the facets of this rich literature. The long tradition that examines law as a dependent variable – as a social institution that changes as society changes – will not be addressed here (see Friedman and Ladinsky, 1967; Chambliss, 1964). The role of law as an instrument in globalization, in expansion of capitalist markets, and in international development is quite important, but more suited to an in-depth exploration in its own right (*see* Globalization: Legal Aspects; Law and Development). Similarly, state actors can deploy law to repress resistance and thereby to suppress social change; although the authors touch on this point, this article cannot fully explore law's role in suppression and social control (see Barkan, 1984; Fernandez, 2008; *see* Control: Social; Nazi Law).

Even within these constraints, law as an instrument of social change is a complex, fascinating, and controversial subject. William Graham Sumner argued that "legislation cannot make mores," because laws that conflict with established social customs and norms cannot change them and are doomed to fail (Sumner, 1906: p. 77). Although prominent failures spring to mind – prohibition is one (Gusfield, 1986) – counterexamples are also easy to identify. These include the legal and social changes associated with the civil rights, women's rights, and disability rights movements; environmental protection legislation; gay and lesbian rights reforms; and even antismoking legislation (*see* Civil Rights Movements; Law and People with Disabilities; Environmental Movements; Gay and Lesbian Movements). Even though law sometimes faces backlash and resistance in the polity (Krieger, 2000; Klarman, 1994; Rosenberg, 1991), in many instances legal change precedes social change and shifts in public opinion, and these legal changes affect both social relations and social meaning. How have those changes come about? Answering this question requires a clear idea of what is meant by 'law' and 'social change.'

Defining Law

The concept of 'law as an instrument of social change' treats law as an independent variable that influences or causes changes in society. Research in this area conceptualizes law in many different ways. One approach is to focus on formal law, in the form of statutes, landmark judicial opinions, constitutions, and the like, to investigate how changes in formal law may bring about social change (see, e.g., Burstein and Edwards, 1994; Keck, 2009; Rosenberg, 1991). Much of this literature focuses on litigation, particularly impact litigation by social movements, and asks whether litigation is an effective strategy for bringing about social change (for a brief review, see Albiston, 2011). There is no consensus on the answer to this question.

A second approach follows the legal realist tradition (Fisher et al., 1993), expanding on the conception of 'law' to include the law in practice in courts, bureaucratic settings, and other settings (Blumberg, 1967; Feeley, 1992; Lipsky, 1980; Frohman, 1997; Ewick and Silbey, 1998). In this view, law includes not only the formal language of the statute, but also how that language is implemented, interpreted, and understood by institutional actors in the state or by individuals in everyday life. Formal law, in this conception, may have little social relevance because social and institutional processes affect how the law is translated into action. In addition, institutional relationships and incentives may produce unexpected and unintended consequences for legal reforms. In an early exemplar of this approach, Blumberg (1967) set out to examine how the US Supreme Court decisions in *Miranda* and *Gideon*, which provided new procedural protections and legal representation for criminal defendants, affected proceedings in American criminal courts. By studying

these legal changes on the ground, Blumberg discovered that long-standing relationships among prosecutors, judges, and defense counsel limited and distorted the impact of these decisions, pushed defendants into plea bargains, and prevented formal legal changes from doing much to improve criminal proceedings in the courts.

A third approach, often labeled the constitutive view, contends that 'law,' or 'legality,' is constructed through social interaction, wherein people mobilize legal concepts and language outside the courts to negotiate conflict or to interpret their experiences (Ewick and Silbey, 1998, 2003). The institutionalized legal meanings that emerge from these interactions become part of a broader cultural repertoire on which individuals may draw to understand and interpret social life, although legal meanings, once institutionalized, also constrain future interpretations (see Swidler, 1986; Sewell, 1992). In this view, law is defined to include customary practices that convey lawlike meanings, such as placing a chair in a newly shoveled parking place after a Boston snowstorm to mark 'personal property' even when no legally enforceable formal right exists (Ewick and Silbey, 1998). Constitutive scholars define law culturally, referencing the work of early legal anthropologists such as Malinowski, who conceptualized law "as a body of binding obligations, … kept in force by reciprocity and publicity inherent in the structure of society" (Malinowski, 1926: p. 58). This approach resists defining law in terms of Western institutions like courts and legislatures. It requires only that people organize their lives in accordance with implicit rules of behavior that create order within society and are recognized by everyone. Modern scholars, including those in the legal pluralist tradition, contend that law in this broader cultural sense often exists alongside formal legal rules, and may be more important than formal law in the ordering of social interactions (Merry, 1988; Fuller, 1994; Moore, 1973; Macaulay, 1963; Ellickson, 1986).

The way scholars define law can subtly shape their understandings of how law acts to produce social change. Some studies of law and social change take an instrumental approach, conceptualizing law as separate from society. According to this view, law acts upon society by providing remedies for harm, by punishing wrongdoing, by deterring unwanted conduct, by shifting moral values, and by providing a symbol around which to rally. This approach tends to assume that social actors have discrete policy goals that the law helps them attain. In contrast, constitutive approaches see social actors and their intentions as partially defined through legal concepts and constructs. For those who subscribe to this view, law is not separate from society but (at least partially) constitutive of it. Law creates and defines the concepts and categories of everyday life, such as private property, the corporation, the status of marriage, vagrancy, even disability (Sarat and Kearns, 1993). Comparative and historical studies reveal that seemingly natural categories such as these vary across legal regimes and national context (Stone, 1984; Ferree, 2003), and changes in these definitional legal concepts change society by redefining social categories and social meaning (Thompson, 1975). Nevertheless, the constitutive approach can still be seen as conceptualizing law as an agent of social change because law influences culture, even though culture also mediates law's social impact.

These definitional debates teach that institutions, actors on the ground, and widely shared cultural beliefs shape what law will mean in practice. Attending to these mediating factors is crucial to understanding law's effect on social change. The insight that law can be found not only in the courts and legislature, but also in bureaucratic organizations like workplaces and schools, in prosecutorial and police discretionary decisions, and in lawlike social customs and legal understandings that permeate everyday life, opens up many methodologies and locations for studying law as an instrument of social change.

Defining Social Change

Social change, the dependent variable in this inquiry, is similarly tricky to define. A common objective is to measure how society changes as the result of legal change, but there is no consensus about what constitutes social change. Social change resulting from law can include redistributing resources among social groups, reconfiguring social practices and interaction (disputing, collective action, and organizations), or reconstituting social meanings (definitions, constructs, values, and norms). Differences in empirical and epistemological approaches generate differences in conceptualizing social change; for example, studies may rely on quantitative or qualitative measures, and focus on direct or indirect changes resulting from law.

Direct vs Indirect Effects

Some approaches measure social change through the 'direct effects' of law, such as the material legal remedies ordered in judicial opinions. For example, Rosenberg (1991) found that *Brown v. Board of Education*, the landmark US Supreme Court decision ordering school desegregation in the American South, produced very little change in school integration patterns in the years immediately following the decision. Rosenberg's straightforward approach immediately drew criticism that choices about how to measure social change were highly subjective, and the choice of measurement heavily influenced the researcher's conclusions (Feely, 1993). For example, should the degree of social change be measured by comparing the results of litigation with the ideal outcome promised in the formal law (see, e.g., Rosenberg, 1991)? By comparing the results of litigation with the goals of the advocates, who brought the case to the Supreme Court (see, e.g., Feely, 1993)? By comparing the results of litigation with the status quo, had the case never been brought (see, e.g., Keck, 2009)? These are not just technical questions; they are deeply normative questions about what counts as meaningful social change.

Moreover, direct effects do not exhaust the possible social changes resulting from law. Rosenberg also considered some 'secondary' or 'indirect' effects of the Court's decision. Although he found no change in broad public opinion after *Brown* (Rosenberg, 1991), Rosenberg did find that *Brown* generated significant and concerted resistance from Southern supporters of segregation (Rosenberg, 1991: pp. 84–85), suggesting that rather than undermining segregation, *Brown* may have reinforced Southern commitment to it. Once again, critics

argued that evaluating these immediate changes did not exhaust the possible indirect effects of *Brown*. For example, the decision may have provided political cover that enabled legislative and executive action in the decade after *Brown*. It may have mobilized social movement protests against Jim Crow in the 1960s (Polletta, 2000). It may have empowered federal judges in the south, who had lifetime appointments, to rule for the plaintiffs in future cases (Klarman, 1994; McCann, 1993).

In a helpful discussion, Galanter (1983) lays out several ways in which courts and law might change society indirectly, through what he calls "general effects." General effects come in many forms, from using legal penalties to encourage potential law breakers to avoid crime, to changing people's rational, moral, or cognitive evaluations of a given social behavior. For example, criminalizing drunk driving stigmatized the practice and made it much less commonplace. Galanter conceptualizes this process as "enculturation," or the widespread shifting or intensifying of moral evaluations of prohibited conduct such as discrimination or smoking (see also Berkowitz and Walker, 1967). Galanter also discusses how litigation mobilizes collective political action by "provid[ing] symbols for rallying a group, broadcasting awareness of grievance[s] and dramatizing challenge[s] to the status quo" (Galanter, 1983: pp. 125–126; see also McCann, 1994; Barkan, 1980). In this view, social change should be understood to include not only material remedial gains for the litigants of a case, but also an emerging oppositional consciousness among activists and the public (Morris and Braine, 2001; Marshall, 2003).

Positivist vs Constitutive Approaches

Another issue in defining social change is the distinction between positivist versus constitutive conceptions of where to look for, and how to measure, social change. Positivist accounts tend to conceptualize social change in terms of discrete, easily measured dependent variables associated with changes in the law, such quantifiable measures of shifts in public opinion (Rosenberg, 1991), or changes in material circumstances (Klarman, 1994; Burstein and Edwards, 1994). Rosenberg's numerical data about integration of schools and shifts in public opinion are an example of this positivist approach. In contrast, constitutive accounts address how law shapes social relationships and conceptions of identity in everyday life (McCann, 1996; Engel and Munger, 2003). For example, the Americans with Disabilities Act (ADA) may produce more accessible buildings and Braille signs, changes that positivist accounts would readily recognize, but it also affects how one understands social relationships and social identities. The ADA changes employers' expectations and attitudes about the resources and services they should provide to impaired employees, constructs 'disabled person' and 'worker' as compatible identities, and changes impaired individuals' conceptions of themselves away from 'spoiled' identities (Goffman, 1963) toward a normalized and agentic conception of self (Albiston, 2010; Engel and Munger, 2003). Here, social change is located in changing meanings, identities, and expectations about social relationships, and not merely in the measurable number of newly added wheelchair ramps and Braille signs.

The way social change is conceptualized affects conclusions about the law's ability to produce it. Narrow measures of social change may yield pessimistic conclusions, whereas broader definitions of social change may produce more optimistic conclusions. Rosenberg's focus on the actual school integration and public opinion immediately following *Brown* provides a narrow snapshot of *Brown's* potential social impact, and his resulting assessment that *Brown* produced little social impact is therefore unsurprising. Broadening the frame of observation to include alternative measurements of social change – for example, expanding the time frame, seeking out the decision's other indirect consequences, or incorporating more qualitative data – may produce different results. Although Rosenberg's work has been a lightning rod for criticism, it has also sparked a rich literature about how to conceptualize social change. As a result, researchers have begun to explore multiple methods and locations for studying social change: quantitative measures of public opinion, changing material conditions, or organization characteristics; qualitative study of changing social meanings and the processes through which legal changes affect social movements and relationships; and ethnographic studies of changing practices and social meanings in particular social settings. Triangulating these measures, and understanding when and why they differ from one another, define the state of the field on this issue.

Mechanisms through Which Law Brings about Social Change

With definitional questions out of the way, one asks: What are the mechanisms through which law might bring about social change? What are the conditions under which law can change society, or fail to do so? Assessing how courts, and by extension law, can change society requires evaluating the resources and capacities of various audiences as well as the indigenous law-like conventions in social locations subject to law (Galanter, 1983). Law's instrumental effects on society are mediated by the actors who mobilize law, the institutions through which law is implemented, and the already-existing social order law seeks to change. Very few laws are self-enforcing; law must be mobilized to be effective. A victim of discrimination, for example, is unprotected under civil rights laws until he or she initiates legal action demanding that his or her rights be enforced. However, mobilizing the law often requires not only specialized knowledge about the law (or access to someone who has it), but also enough independent wealth to invest the time and money into pursuing a claim – unrealistic expectations for many if not most citizens. Furthermore, practical concerns, such as the need to maintain social relationships, as well as social norms can inhibit people from taking action to enforce legal rights (Bumiller, 1987; Morgan, 1999; Quinn, 2000). Obstacles like these may limit law's effectiveness for social change because courts generally decide only the legal questions that parties bring to them. To illustrate, the authors will discuss three foci of the law and social change literature: the rights debate about the utility of litigation for social change, law and social change in organizations, and how social movements mobilize law to pursue social change.

The Rights Debate

The Rights Debate refers to the debate among scholars about the utility of rights litigation as a strategy for social change. *Brown v. Board of Education* was a catalyst for studying these questions because the strategic litigation campaign that let up to *Brown* is the paradigmatic example of mobilizing law to change society. Several scholars tout how the NAACP's litigation strategy brought about social change even in the absence of significant political clout (Kluger, 1976). In this view, underrepresented communities that lack meaningful access to the polity nevertheless can change social policy through legal strategies (Zemans, 1983). This view is sometimes labeled 'liberal legalism': the idea that constitutional and legal boundaries constrain politics, and therefore legal claims provide a powerful mechanism for producing equality and social change.

Liberal legalism has come under attack from scholars skeptical of the utility of litigation for social change. For example, Scheingold (1974) coined the term 'myth of rights,' the recognition that rights are not self-executing but must be mobilized to be effective. Empirical research soon demonstrated that mobilization was the exception, not the rule (Miller and Sarat, 1981). From the myth of rights perspective, rights litigation undermines collective action by atomizing collective grievances into individual problems and narrowing grievances to only legally actionable claims (McCann, 1986; Scheingold, 1974). Empirical research suggests that litigation fails to produce lasting social change because courts lack institutional authority to implement radical reforms (Rosenberg, 1991), legal victories can be evaded or dismantled without a sustained movement toward reform (Handler, 1978), and powerful opponents retain strategic advantages even within a formally neutral legal system (Galanter, 1974; Albiston, 1999). Rights litigation can even be counterproductive because it legitimates a legal system that masks inequality by seeming to provide a remedy while producing little substantive change (Freeman, 1982, 1998; Tushnet, 1987).

Other scholars responded to this forceful critique of liberal legalism by advancing a more optimistic view based on the symbolic and strategic utility of rights litigation. In this view, rights litigation can change social meaning and give individuals symbolic recognition and personal dignity (Engel and Munger, 2003; Williams, 1991). Even if legal victories are hard to enforce and maintain, rights litigation also mobilizes social movements working outside the legal system to bring about change. For example, McCann, in his study of the US Equal Pay Act movement, finds that pay equity litigation crystallized an issue around which activists mobilized, attracted media attention and participants to the movement, and changed participants' conceptions of what might be possible (McCann, 1994). More instrumentally, the threat of rights litigation can provide leverage in negotiations and publicly embarrass opponents (McCann, 1994: pp. 140–153). Some of these mobilizing effects can occur even when litigation is unsuccessful (McCann, 1994; NeJaime, 2011). Thus, from this perspective, rights litigation affects more than legal outcomes because it can motivate activists to utilize additional avenues of change, such as protest or legislative advocacy (McCann, 1994; NeJaime, 2011).

This debate about rights and social change engendered a much broader understanding of the mechanisms through which law brings about social change, and an expansive view on the locations in which change might occur. Scholars have moved beyond a narrow focus on court-imposed legal remedies to consider movement-building effects, the development of oppositional consciousness, cover for legislative and executive branch actors to make significant changes, media attention and public agenda setting, the formation of collective identities, changes in everyday understandings and social interactions, and even changing perceptions of self-identity. These outcomes are highly interconnected, often triggering and reinforcing one another and driving mechanisms for even broader social reform.

A second important insight is that law may not have the same effects in all social locations. For example, research focusing on litigation in the courts suggests mixed outcomes. Some research suggests civil rights plaintiffs are relatively successful, while other research finds little material change following landmark court decisions (Rosenberg, 1991; Burstein and Monaghan, 1986; Burstein, 1991). Other research focused on everyday locations suggests that even informal rights mobilization can bring about change or even become a catalyst for collective action (Albiston, 2005, 2010). Similarly, some scholars find law positively constructs identity (Engel and Munger, 2003), whereas others find that claiming rights imposes too great a cost by requiring claimants to recognize an injury and identify as a victim (Bumiller, 1987; Quinn, 2000). Although this literature offers no easy conclusions about law as an instrument of social change, it does highlight the rich set of mechanisms and locations through which law may change society.

Organizational and Institutional Resistance

Organizational settings such as schools, prisons, or employers are major targets of legal reforms, but law does not penetrate organizations automatically, without cost or distortion. Neo-institutional organizational theory treats organizations as open systems that respond to their environment, including law, in complex ways that tend to produce homogeneity among organizations in the same organizational field (Meyer and Rowan, 1977). Organizations tend to be isomorphic, or similar, in their structure and practices because they operate under a shared system of rules – regulations, norms, and cognitive schemas – derived from a common social environment (DiMaggio and Powell, 1991). Legal institutions are part of that environment, and isomorphic processes are thus a mechanism through which law changes society, or at least organizations in society. Law facilitates 'coercive isomorphism' by imposing similar, sanction-backed legal requirements on organizations in the same field, such as the tax code rules governing the structure and activities of nonprofits (DiMaggio and Powell, 1983: p. 150). Isomorphic processes can also be 'mimetic,' when organizations in the same field respond to ambiguous legal requirements by adopting the practices of other organizations that they perceive to be successful (Edelman, 1990). A third mechanism, 'normative isomorphism,' occurs when professionals who have similar training, such as lawyers or human resource managers, diffuse

common practices through professional associations and then bring those practices back to the organizations of which they are a part (DiMaggio and Powell, 1991). Often legal values such as due process provide professionals normative guidance in determining which practices are legitimate and effective (Edelman, 1990).

Each of these processes can affect whether law will influence existing organizational processes or become marginalized to prevent interference with other organizational priorities. For example, in response to coercive legal rules, organizations may offer symbolic compliance in the form of policies and structures visible to actors outside the organization but only loosely coupled to actual practice within the organization (Edelman, 1992; Orton and Weick, 1990). Internally, organizations may interpret and implement legal mandates in ways consistent with managerial objectives but inconsistent with legal norms and mandates (Edelman, 1992; Albiston, 2005). When legal requirements are ambiguous, organizations may turn to others in their field to identify compliance strategies that will confer legitimacy, even if those strategies were largely determined by the organizations themselves and not the requirements of law (Edelman, 1990, 1992). These strategies then diffuse throughout organizational fields and become institutionalized as the meaning of compliance (Edelman et al., 2001, 2011). Normative isomorphism operates through professionals who learn common practices through professional training and associations and then bring those practices back to the organizations in which they work. Through this mechanism, professionals may help diffuse widespread but inaccurate myths that drive organizational behavior in a homogenous but irrational direction. For example, Edelman (1992) found that human resource professionals exaggerated the risk of employment discrimination suits compared to their actual incidence in the courts. Over time, organizational definitions of what constitutes compliance often find their way into legal doctrine because judges defer to widespread organizational practices as evidence of compliance without probing whether those practices have any tangible effects on life within the organization (Edelman et al., 2011).

These processes produce organizational structures and practices that respond to law but do little to bring about social change. Once these practices and norms become institutionalized, they become difficult to dislodge through subsequent legal change, creating barriers to social change (Kelly, 2010; Albiston, 2005). For example, Kelly (2010) found that, in the United States, noncompliance with the Family and Medical Leave Act tracked prior institutionalized practices adopted to comply with the Pregnancy Discrimination Act, even though the law had changed to allow fathers as well as mothers to take leave. Organizational norms and practices that grow up around social institutions rather than legal mandates can also be difficult to change. For example, Albiston (2005) found that workers faced gendered resistance to family leave consistent with the institutionalized male breadwinner/female homemaker stereotype embodied in standard work schedules, even though statutory leave rights were gender neutral.

When law does penetrate organizations, typically an authoritative agent or organizational actor is involved. Kalev et al. (2006) found, for example, that workplace diversity programs that designated specific organizational actors to take responsibility for compliance were most effective at increasing the proportions of African-Americans and white women in private sector management. Similarly, Albiston (2005, 2010) found that workers who knew their rights could mobilize law as an authoritative discourse to reinterpret the meaning of taking leave and pressure employers to comply. McCann (1994) found that union advocates mobilized the threat of pay equity lawsuits to gain leverage in negotiations with employers. But organizational actors face competing incentives. Managers rewarded for production and profit rather than legal compliance may view lawsuits as simply a cost of doing business, and therefore see noncompliance with legal mandates as a calculated risk in a complex business environment (Stone, 1975). For this reason, organizations do not seem to operate as unitary, rational actors when they respond to legal sanctions. Rather, organizations and organizational actors manage symbols of compliance and the risk of legal sanction in complex and nonintuitive ways.

Social Movements and Law

Although studies of law and social movements typically treat law as the dependent variable – the target of a movement's attempts at change – law can also affect how social movements define their cause, determine their agenda, and choose their strategies for social change. Perhaps the most fundamental way in which law influences social movements is by shaping the social construction of a movement's grievance, or the collective 'naming' of the social problem motivating the movement as unjust and subject to change (Felstiner et al., 1980). This process of collectively cultivating 'oppositional consciousness' is a crucial step in social movement formation (Piven and Cloward, 1977; Morris and Braine, 2001; see McAdam, 1982). Law factors into this process as a set of norms affecting people's understandings of their social world. The law's broad promise to protect people against 'discrimination' and 'inequality' provides a framework for perceiving and articulating injustice (Albiston, 2005; Marshall, 2003) and it encourages the sense that taking action will make a difference (McCann, 1994: p. 89). Legal constructs may also facilitate the perception of social grievances as collective harms. The legal construction of stigmatized identities such as 'criminal' or 'alien' can generate a common political identity among otherwise unassociated individuals who collectively opposed their legal stigmatization (Eskridge, 2001). Rights are another legal construct that movement actors draw on informally to highlight the movement's collective identity or collective experience of harm (Leachman, 2013). For example, women's movements in the United States have articulated collective rights claims in the past that emphasize women's shared vulnerability or common experience of societal discrimination (Pedriana, 2006; McCammon et al., 2007: p. 729; Ferree, 2003: p. 335). In these ways, legal constructions fuel perceptions of injustice and group identity, crucial elements of movement formation.

The legal mobilization literature also views law as a source of resources for social movement activists to mobilize, and these resources affect the movement's organization, development, and ability to survive (McCann, 1994). In this respect, legal mobilization literature parallels the sociological resource mobilization scholarship, which argues that social movements

arise and succeed when they are able to mobilize resources from sympathetic elites or from indigenous sources within the movement (Jenkins, 1983). Rather than focusing on the material resources that movements marshal, legal mobilization scholarship examines how law generates symbolic resources that movement actors use to motivate and rally constituents (Scheingold, 1974; McCann, 1994; Merry and Stern, 2005; Silverstein, 1996; Polletta, 2000; Coleman et al., 2005) or to generate public support for movement goals (Marshall, 2003; see also Jenness, 1999). Movement rhetoric is often rife with references to law, including not just rights claims, but also claims about citizenship, popular sovereignty, and judicial deference (Leachman, 2013). Such legal framing is often an effective way of packaging a movement's demands because the pervasiveness and cultural legitimacy of law make legal language resonate with a wide cross section of audiences (Snow and Benford, 1992; Pedriana, 2006: pp. 1727–1728; McCammon et al., 2007).

Social movement litigation also helps draw attention to injustice and put issues on the public agenda by attracting media coverage. Litigation strategies tend to attract more media coverage than other political tactics (McCann, 1994: p. 62; Silverstein, 1996: p. 198), directing public attention toward a movement's legal demands (see Levitsky, 2006). Movement actors can draw on those high-profile litigation campaigns to encourage donations in fund-raising efforts (Boutcher, 2005; NeJaime, 2011). Movement litigation also tends to attract the attention of political elites (Persily et al., 2007: p. 9), whom activists cultivate as powerful allies (Minkoff, 1999: pp. 1668–1669; Woods and Barclay, 2008) and use to leverage political concessions to movement demands (Handler, 1978: p. 92; Scheingold, 1974; Kolb, 2005). These studies illustrate the importance of linguistic and media resources both in their own right and as mediating mechanisms that generate additional material resources.

Third, the law shapes social movements' 'tactical repertoires,' the set of practices available to activists to accomplish movement goals (see Ennis, 1987). Law as a set of formal rules and procedures affects the availability of litigation as part of movements' tactical tool kit. Legal changes in the rules of standing opened up decades of environmental protection litigation that otherwise would not have been possible (Orren, 1976). Similarly, civil rights statutes provide a legal means to redress grievances about discrimination in employment and suppression of the franchise among minority communities (Albiston and Nielsen, 2007). Formal law may catalyze extralegal mobilization when a landmark judicial opinion generates a sense of hope or outrage (Andersen, 2005: p. 44; see Rosenberg, 1991: pp. 155–156). Litigation strategies may encourage a movement to undertake other forms of political action and grassroots organizing (McCann, 1994), for example, by providing a concrete focus or goal to demand (Boutcher, 2005; Coleman et al., 2005; McCann, 1994; Polletta, 2000).

Social movements that employ legal strategies may pay a price, however. Litigation is expensive, and may drain social movement resources away from potentially more effective strategies, such as protest or grassroots organizing (Rosenberg, 1991; Scheingold, 1974; see Hunt, 1990; but see Polletta, 2000). Although statutory individual rights provide a mechanism for addressing injustices such as discrimination, they tend to channel grievances into individualized litigation and discourage collective action (McCann, 1986; Scheingold, 1974). Litigation success, in part because of its visibility, may also mobilize a countermovement or cause the opposition to systematically resist legal reforms (Rosenberg, 1991; Klarman, 2005; Luker, 1985).

A price also may be exacted at the level of social meaning, identity, and the very definition of the cause. Using litigation as a social movement tactic can deradicalize the message and objectives of a movement, even if the litigation is successful. Existing legal rights and rules form discursive opportunity structures through which social movements may advance their causes. To access these opportunity structures, movement actors must shape their claims and demands to fit available legal templates. Because law is a relatively conservative institution, fitting claims to law's discursive opportunity structures risks taming the movement's demands and deradicalizing its agenda (Ferree, 2003). Furthermore, the law's ability to attract resources may support lawyers as movement leaders and make litigation strategies dominant, moving more confrontational strategies such as protest to the margin (see Haines, 1984). In turn, lawyers as elite actors can reshape movement messages and goals even when the broader movement's participants have different goals (Bell, 1976; Levitsky, 2006).

When identities are legally protected, litigation tactics tend to shape and define the identities around which movements mobilize, even if those legally expedient identities are not the ones activists or individuals would choose outside of law. Bumiller (1987) found, for example, that individuals who believed they had been discriminated against were reluctant to mobilize legal claims because they resisted taking on a victim identity required by discrimination law. Some gay and lesbian activists note how the pursuit of same-sex marriage has required plaintiffs to conform to a near-heteronormative family status to obtain legal rights, even though some movement activists would prefer to broaden the definition of who counts as family (Polikoff, 2008). Incremental social change, in this view, comes at the expense of more radical and far-reaching changes in how one understands identity and social relationships. Thus, when evaluating law as an instrument of social change, it is critical to consider which demands may have been marginalized or abandoned because a social movement relied on legal tactics rather than other mechanisms of social change (Albiston, 2011).

Conclusion

Sociolegal literature provides no definitive conclusions about the law's role as an instrument of social change, but it has provided researchers with guidelines for constructing a more nuanced understanding of the relationship between law and social change. The literature has moved beyond questions of whether law matters for social change toward investigating the ways in which, and the mechanisms through which, law influences social change. The research also has moved toward identifying multiple forms of social change, including material and symbolic changes, as well as direct and indirect changes, and toward theorizing the relationship among these forms.

Scholarship addresses the law's ability to generate social change in disparate social contexts and the various cultural and institutional factors that shape what law will mean in practice. These questions involve looking at the relationships among legal meanings, the social practices structured around those meanings, and the institutionalization of legal understandings that can promote radical change or retrenchment. The productive empirical work investigating these processes provides important theoretical frameworks for understanding how systematic factors may enhance or constrain the potential for social change through law.

Law as Constitutive

Roger Cotterrell, University of London, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

'Law as constitutive' refers to the idea that law helps to constitute the social world by shaping culture and social relations, and by helping to determine popular understandings and common sense. The idea contrasts with early approaches in sociology of law that typically saw law as itself largely controlled by wider social forces. To emphasize law's constitutive power is to recognize its social significance, but also to risk exaggerating this. Productive approaches will be ones that view law pluralistically as a facet of social experience, shaping and being shaped by other social phenomena, and integrated with them in complex and variable ways.

The idea of law as 'constitutive' is the idea that law not only regulates but also can create or determine social phenomena. According to this view, law shapes fundamental, moral, or political assumptions and general conceptions of the nature of social relations and social institutions. Jurists and some social theorists have long argued that law has a major role in defining basic social understandings of property, responsibility, and personality. The views of law's constitutive capabilities that have been developed in Marxist theory and in critical legal studies mainly stress law's conservative social power. They contrast with other sociological views of law as a relatively passive reflection of social forces, or as an instrument of government consciously aimed at producing social change. The major problem of the focus on law as constitutive is its tendency to exaggerate or assume law's independent social power, especially when law is treated exclusively as juridical regulation by the state. Wider 'pluralist' views of legal experience, however, offer possibilities for sophisticated analyses of law as both constituting and being constituted by other social phenomena.

The idea that law not merely regulates but also creates or forms social phenomena has been a powerful component of recent sociologically oriented approaches to the study of law. Yet it is an old idea that has resurfaced in social science and legal studies after having been marginalized through much of the modern development of sociology of law in the second half of the twentieth century (see Sociology of Law). In its recent forms, the idea of law as constitutive focuses particularly on law's power to shape fundamental, moral, or political assumptions, elements of culture, and general conceptions of the social. In this sense, law is seen as a mechanism shaping consciousness, establishing frameworks of thought and evaluation in terms of which social life is structured.

Classic Conceptions

Classic legal sociology, represented especially by the work of the Austrian jurist Eugen Ehrlich at the beginning of the twentieth century, confronted the constitutive role of law as an urgent political question: to what extent can the law of the nation-state define the nature of social relations in the face of powerful competing moral forces (Ehrlich, 2002). In a multicultural society (such as the disparate and fragmented Austro-Hungarian empire of Ehrlich's time) in which diverse religious and ethnic influences on social life remained strong and sometimes antagonistic to the values enshrined in state law, Ehrlich concluded that state law's constitutive power is limited and it must learn from, as much as seek to control, informal norms of social life (Hertogh, 2009). Many other theories in the formative era of modern legal sociology carried similar messages: of law either rooted in existing culture and established collective understandings or enfeebled by its separation from them. The idea is expressed in W.G. Sumner's (2002) view in 1906 that effective legislation must be consistent with social mores, in Roscoe Pound's (1917) insistence on the 'limits of effective legal action,' and in persistent echoes of Friedrich Carl von Savigny's (2002) claim in 1814 that law must be rooted in a "common consciousness" (*Volksgeist*) of the people, which it expresses but cannot change.

According to all such views, because law is strong when it represents popular understandings and weak when it runs counter to them, its power to constitute social relations is circumscribed. Law has a degree of independent social power only insofar as it avoids intruding on matters of belief or deep-rooted traditional practice; technically oriented law can be effective, while expressive (ideologically charged or value-infused) law is relatively weak unless the values and understandings it presupposes are already in place in social life.

Thus, an important agenda for sociology of law in the second half of the twentieth century became the exploration of conditions under which law's regulatory techniques could be used to bypass the assumed inertia of culture or to shape specific kinds of social relations in ways that might indirectly encourage more general social change. In an era (especially from the 1960s) in which urgent attempts were made to harness law to tasks of social engineering (e.g., in preventing racial and sexual discrimination), the old idea that law could only mirror established systems of values and beliefs symbolized a serious problem to be addressed. Legal sociology's practical task became to confront cultural obstacles that stood in the way of the successful use of law to induce social change. Law as an instrument of social control or social transformation might be able to operate instrumentally if appropriate regulatory techniques could be devised and conditions were favorable, but law remained limited by its cultural dependence, its general lack of power to constitute popular understandings, values, and beliefs.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86056-0

Classical social theory supported this view of law as culturally dependent only obliquely and partially. Émile Durkheim's sociology treats law as merely one dimension of a larger moral universe (see Durkheim, Emile (1858–1917)). Law neither constitutes nor is constituted by moral understandings and moral bonds but is an aspect of them; it is these bonds and understandings that constitute society (Cotterrell, 1999). Max Weber, associating modern law with a particular kind of rationality, sees law as running parallel in its development with other kinds of rational reordering of Western experience (Kronman, 1983), although his sociology remains ambiguous as to the nature of law's specific contribution to a more general modern 'rationalization' of life (see Weber, Max (1864–1920)). Karl Marx's conception of law as part of the superstructure of a mode of production (see Marx, Karl (1818–83)) is also ambiguous as to law's 'independent' constitutive role, but suggests that this role will, at best, be limited (Collins, 1982). Thus, while law may provide indispensable support (ideological and repressive) for a mode of production, it cannot, according to standard Marxist analyses, constitute such a mode or change it in any historically fundamental way. Nevertheless, law constitutes, in the sense of formalizing and defining, relations and understandings of contract and property. To that extent, it contributes powerfully to ideology in capitalist societies.

Modern Critical Perspectives

The Marxist-derived idea of law framing consciousness (by shaping ideas of responsibility, ownership, freedom, consent, agreement, causality, authority, etc.) has strongly influenced recent ideas about the constitutive power of law, especially as a result of its advocacy as a central tenet of the modern critical legal studies (CLS) movement. CLS, which developed in many Western countries and especially in the United States from the 1970s, had a major influence on destroying old ideas of law as a passive reflection of other social forces (see Critical Legal Studies). Its effect on sociology of law was to help to turn attention from questions about how law might be made more effective as an instrument of social change and toward studies of law's power to reinforce established social practices and institutions, primarily by influencing collective understandings. Thus, because of the continual invocation of basic legal concepts, especially of property and contract, in everyday regulatory practice, law, in the CLS view, contributes importantly to the 'reification' of concepts, that is, the turning of debatable ideas into settled, widespread, usually unchallenged understandings.

Property, for example, ceases to be a variable relationship and tends to become a virtually sacred private object (described in terms of its 'sanctity'). Early in the nineteenth century, Jeremy Bentham (2001), the founder of modern Anglo-American legal philosophy (see Bentham, Jeremy (1748–1832)) had insisted that 'property' is one of many 'fictitious entities' created by law (others include 'right,' 'duty,' 'power,' 'immunity,' 'privilege,' and 'liberty'), but in modern liberal societies property is commonly understood as antecedent to law and law is viewed as the protector of property, not its creator. CLS, indirectly following in the footsteps of Bentham and other pioneers such as the French jurist Emmanuel Lévy (Cotterrell, 2008), treated legal concepts and reasoning as having the power to create and sustain fundamental ways of thinking about social relations.

Marxist legal theory in its most sophisticated forms (e.g., Pashukanis, 1978) and modern critical legal theory emphasize that law shapes ideas of personality and subjectivity, which influence much wider currents of social thought. Thus, law defines who can be responsible for actions and who can engage in transactions that will be legally recognized. In particular societies at particular times, children, married women, mentally handicapped people, prisoners, and aliens of the state (foreigners) have been treated as wholly or partly lacking legal capacity (e.g., to own property directly). Thus, for certain purposes, law constitutes human capacities or denies them. Correspondingly, law routinely gives personality and capacity to nonhuman entities. In various societies, these have included religious idols and animals, but in modern law by far the most important example of the construction of nonhuman personality is the attribution of legal personality to the business corporation. This attribution constitutes the corporation as an entity entirely separate from the human individuals who work for it. In recent critical legal scholarship, the concern with law's constitution of personality has broadened to focus on the wider range of effects of law on the construction of identity.

Feminist theory has emphasized that law has typically constituted the human person in terms of male characteristics. In the past, this legal stance was often explicit, with the denial in legal doctrine of women's legal personality in certain contexts (e.g., as property owners or voters). Modern feminist theory has shown how legal thought and practice ignore differences between women's and men's experience, or covertly assimilate the former to the latter, applying a 'male standard' to the definition of all social relations, capacities, and responsibilities. It has been claimed that law constructs women (in its typical rhetoric and evaluations) as 'terrorized, sexualized and maternalised' (Frug, 1992). In a host of studies, critical sociolegal scholarship has also focused on the legal construction or denial of the social identities of minority groups (e.g., López, 1996) and, more generally, on law's power to define and exclude 'the other' in sharp opposition to an image of the 'normal' subject of law.

The effect of this accumulation of critical work is a widespread rejection among sociolegal scholars of the doubts about law's social importance that long haunted legal sociology. In their place is a confidence that legal ideas and practices are central matters for sociological study. The older legal sociology sometimes slipped into the self-defeating position of holding that law 'mirrored' society (thus implying not only law's lack of social scientific importance but also its 'nonsocial' identity as 'merely' technical regulation and so its substantial immunity from conceptualization as a social phenomenon in itself). The newer emphasis on law as constitutive asserts law's power to shape fundamental collective understandings and practices that define the nature of social life. Taken to extremes, this position can suggest that law constitutes the very idea of society, as opposed to society constituting law (Fitzpatrick, 1995). A further step might be to discard all reified conceptions of 'society' or even of 'the social' as a category (on the basis that the social picture is now too fluid and complex to allow such

encapsulations or to allow these concepts to retain analytical power). The aim then would be to focus specifically on the particular kinds of social conceptions (e.g., of identity, community, and culture) that legal doctrine itself proposes, assumes, or sustains. In a sense, such an approach entirely reverses the conception of law as mirror of society: the social (whether or not it remains possible to conceptualize this as any kind of totality) is seen as the construction of law.

As scholars and policy makers in Western societies are once again seeking ways to effectively regulate their economic and financial systems, partly as a consequence of acute economic crises, the question of how far law can shape the culture of business corporations and economic and financial networks has entered many recent agendas of research. Sociolegal scholars have suggested that law can operate not only through direct regulatory controls on institutions, procedures, and transactions but also by reinforcing templates of ethical behavior so as to help alter and shape attitudes within corporations and to influence business cultures. Some writers propose that such 'endogenous' effects of law can coexist with processes by which law also learns from business cultures (Edelman and Stryker, 2005). So if law can, to some extent, constitute culture indirectly, it may also be constituted partly by the culture it addresses. It might be said that it learns as it teaches.

Limitations of Constitutive Approaches to Law

A danger of constitutive approaches is that of greatly exaggerating law's power (how can we know that *law* does the constituting and, even if it does, under what conditions and constraints?). Jurists have long been tempted in this way, some even speculating that law largely determines morality by contributing to socialization (Olivecrona, 1939). Philosophers and jurists note law's 'word-magic,' the power of legal words as 'performatives' to bring about social effects, such as inaugurating marriages, creating personal statuses, or transferring property (Austin, 1982). But these formal effects raise rather than answer questions about law's social character. The risk is of attempting to analyze law in isolation from other social forces, treating it (as the earlier 'mirror' conceptions tended to do) as separate from other aspects of social life, with a causal relationship existing between law and society. This danger has been especially serious for CLS, which, being essentially a law school movement rather than a movement in social science, has tended to assume law's social significance and power (in conformity with the main trend of lawyers' thinking throughout modern times) rather than to seek to assess it systematically and empirically in a wider social context.

Equally, it is not always recognized sufficiently that law's constitutive power may vary greatly in different societies. In some societies, its power to shape ways in which politics is conducted (Balkin, 2011), or in which social movements are formed and their campaigns or collective strategies are pursued (Brigham, 1996), may be very clear, if complex in its effects. In other societies, different cultural values and traditions make law much less capable of constituting the form and character of social relations. Indeed, they might make it largely irrelevant.

It is also significant that one influential and sophisticated theoretical approach in contemporary legal sociology entirely rejects the idea of law as constitutive of society because it denies that law as a system can communicate with, and so influence, wider social life in any direct way (Luhmann, 2004). Autopoiesis theory sees modern law as a discourse that normatively constitutes (more specifically, produces, reproduces, and observes) only itself. One consequence is that its conceptions of agency, responsibility, personality, subjectivity, and so on are produced solely for its purposes and processes and have no necessary relation to anything existing outside these. Far from constituting economic, scientific, political, or cultural life, law produces decisions to which these other social systems may respond on their own terms. Autopoiesis theory denies all conceptions of law as a mirror of society. At the same time, its assertion of law's radical discursive autonomy deliberately provokes endless questions as to how law can engineer social effects that are other than intolerably unpredictable.

The Plurality of Legal Experience

Some recent sociolegal approaches have discarded both the idea of law as a mirror of society and that of law as a more or less independently constitutive force in social life, and replaced these with a view of law as social mediation (e.g., Mertz, 1994). Law thus appears as one way (or perhaps a cluster of ways, if it is not seen as a unitary discourse or practice) in which social experience is mediated, conceptualized, defined, and evaluated.

Such an approach presents its own difficulties as a sociological conception of law. If law mediates the social in some way, what enables it to do so, and from where does its power or authority to mediate derive? What is the nature of law if it is, in some way, separate from the social life that it mediates? The questions are ultimately no different from those that haunt the idea of law as constitutive (e.g., where does law derive its power or authority to constitute social life? And how, in what way, is law separated from social life in order to constitute it?).

In answering these questions, the temptation is often to dissolve one term into the other. Thus, law may be seen as, for all practical purposes, constituting the social so that the latter ceases to exist (at least for purposes of sociolegal analysis) as something independent of legal categorizations and evaluations. On this view, law may certainly be studied in social context, but its significance as an object of study requires no validation by social science. Alternatively, law can be seen merely as a mirror of social forces and social structure, meriting no special, independent sociological analysis. On this view, juristic concerns are socially insignificant unless reducible to general sociological categories and concepts.

A productive approach may be available to avoid both of these positions. Law is sometimes conceptualized sociologically as an aspect or field of social experience. In this sense, it is a component of social consciousness, a normative patterning of experience, or a framework of understandings or practices. As an aspect of social life, it is to be separated from other social phenomena only provisionally and contingently for purposes of study (Cotterrell, 2006). Important antecedents of this approach exist in legal sociology (Gurvitch, 1947), but they

have been obscured, to some extent, by approaches that treat law entirely as an instrument of the state. Viewed in this state-focused way, law's constitutive power appears problematic or mysterious given (1) the state's frequently noted remoteness from the local milieux it regulates, and (2) the increasing production of law by agencies other than the state.

Law may, however, be understood pluralistically as existing not only in the practices and procedures of state agencies, but also in the everyday circumstances, sites, and settings of a wide variety of social groups and networks (see Legal Pluralism). Legal experience, according to this view, is the subjective experience of individuals and groups confronting, in these diverse environments, 'local' issues of governmental regulation and social control. An approach along these lines will see law as constituting social life insofar as it is itself embedded in social life, in expectations about security, responsibility, and other matters. At the same time, state law (the legal practice of lawyers and courts serving the centralized state) needs to be not merely politically constituted, according to criteria of political legitimacy, but also (from a pluralist perspective) morally constituted by its relation to the social experience of the populations that it purports to regulate (Cotterrell, 2006: 34–44). From this perspective, the issue of law's moral authority, identified by Ehrlich a century ago, still remains crucial for modern law.

Abstract

The term autopoiesis is a key concept that has been adopted by modern sociological systems theory in explaining the nature of social systems as communication systems that are capable of reproducing themselves. Legal autopoiesis (self-reproduction) results from processes of hypercyclical self-constitution within the legal system. The modern legal system operates with reflexive forms of regulation that recognize the autopoietic nature of both the legal system and the regulated systems. Modern law is increasingly becoming global law and is engaged in double reflexivity by responding to processes of societal constitutionalization in various function systems and regimes in the world society.

Legal autopoiesis refers to the idea that the legal system presupposes and reproduces itself. Modern sociological systems theory employs the concept of autopoiesis to emphasize the self-constituting nature of social systems. In analyses of the legal system, it constitutes a hybrid form of a legal theory and a sociological account of law.

Autopoiesis and the Functionally Differentiated Society

Autopoiesis describes the capacity of an entity to reproduce itself. As a concept, it was first introduced in theoretical biology to explain cognition and the essence of life (see Maturana and Varela, 1980) and was then further developed in general systems theory (for example, von Förster, 1984). It has been widely applied in mathematics, in the study of cognition, and in studies of the nervous system as well as in information systems, cognitive science, and artificial intelligence (see Mingers, 1995).

In general systems theory, the following definition is widely accepted: autopoietic systems "are defined as unities and as networks of production of components that recursively, through their interactions, generate and realize the network that produces them and constitute, in the space in which they exist, the boundaries of the network as components that participate in the realization of the network" (Maturana, 1981, p. 21). Maturana's definition operates with a notion of recursive closure of the system. An autopoietic system is not only able to produce and eventually to change its structures, but is also capable of reproducing its components, and in particular its system-specific elements, through recursive self-reference of these elements. Thus, its self-reproduction relies exclusively on internal operations and is not dependent on the environment.

Niklas Luhmann (1927–98) (*see* Luhmann, Niklas (1927–98)) is responsible for introducing the concept of autopoiesis to social systems theory (Luhmann, 1986; see also Luhmann, 1995, 2012). His approach transcends the Parsonian version of sociological systems theory, which operates with an input–output model of the social system and its environment. A crucial element of Luhmann's concept is the idea of communications as the ultimate, indecomposable elements of an autopoietic social system. Social systems are capable of reproducing themselves because they are communication systems.

Autopoietic social theory distinguishes between society and functionally differentiated social systems. Society is seen as a first-order social system, whereas the legal system is viewed as a second-order social system or societal subsystem. Society as a first-order social system differs from second-order social systems insofar as it has no other social system as an environment; society's environment consists of natural and psychic systems, i.e., the consciousness of human beings. In fact, human beings do not form part of society or any social system but belong to their environment; the individuality and the consciousness of human beings are features of highly complex psychic systems that operate separately from social systems (Luhmann, 1995, Chapter 7).

Autopoiesis of the Legal System

In accordance with general systems theory, autopoietic legal theory assumes that law is a special communication system that reproduces itself in self-referential processes. Legal communications, such as legal norms, legal decisions, or legal doctrine, are central to the autopoiesis of the legal system (Teubner, 1993; Luhmann, 2004). In order to determine whether a communication is part of the system, the legal system operates with a specific binary code: law/nonlaw or legal/illegal (Luhmann, 1990).

However, the code itself is not sufficient for the creation of law. The code must be translated into legal programs. Furthermore, the creation of law is linked to handling expectations and in particular to dealing with disappointments of expectations. The legal system operates with a specific combination of normative closure and cognitive openness (Luhmann, 1987). It upholds the existing norms and procedures but it is also capable of learning in response to disappointments, and provides mechanisms for its own change (Luhmann, 2014). An important feature of autopoietic legal theory is the radicalization of the notion of legal autonomy. This means that law is conceived not just as being a separate entity in society but that the theory ultimately aims at explaining how this autonomy is the result of internal processes and is maintained over time through closure of the system and self-reference (Luhmann, 1982b). It is the peculiar character of autopoietic law that "only the

law can change the law. This is not to deny that the environment (in particular the political system) has an impact on the legal system. But the legal system reproduces itself through legal events and only by legal events" (Luhmann, 1990, p. 229). On this basis, the modern legal system becomes positive and reflexive.

A further consequence of radical legal autonomy is the emergence of a special legal understanding of the external world. Like other function systems, the autopoietic legal system develops an epistemology according to its own criteria (Teubner, 1989). It is this specific worldview that guides its internal operations and thereby influences legal development.

Legal Evolution and Structural Coupling

The legal system forms part of the functionally differentiated modern society (other function systems include among others the economic, the political, and the religious systems). Each system within society evolves separately along its own trajectory, with its own internal structures and processes determining its development. In explaining the transformation of the legal system into an autopoietic system, Gunther Teubner points to a 'hypercycle' by which internal processes turn law into a self-reproducing system (Teubner, 1993, Ch. 3).

However, the evolution of social systems is not determined exclusively by internal conditions. Specific external relations that derive from structural couplings also have an effect. Structural coupling allows only selective exchanges between the systems. Structural coupling produces irritations and perturbations inside the system that are implemented by the system through its network of operations into further operations (Luhmann, 2013/2014, Vol. 1, Ch. 3).

These perturbations do not actually cause changes; rather, they serve as triggers that may initiate internally controlled operations in operationally closed systems. Thus, structural coupling of social systems does not contribute directly to the reproduction of the systems. It is simply the form in which the system presupposes specific states or changes in its environment and relies on them.

The constitution provides an example of structural coupling between the legal and the political systems (Luhmann, 2004, Ch. 10). When constitutions emerged in the eighteenth century, they helped recombine the functionally differentiated political and legal systems. From an autopoietic perspective, constitutions were adopted in response to problems of self-reference, paradoxes, and asymmetries in the legal and the political systems of the respective countries. In the political system constitutions are the mechanisms of self-binding sovereign power. In the legal system it provides the latter with the power to determine the constitutionality of positive law.

Reflexive Law and Legal Regulation

The concept of reflexive law, which at the beginning arose from a debate with the theory of responsive law, accompanies autopoietic legal theory (Teubner, 1983). Gunther Teubner argued that the modern legal system is characterized not only by formal and substantive rationality but also, increasingly, by reflexive legal rationality. The reflexive law concept was originally intended to combine the social theories of Jürgen Habermas and Niklas Luhmann. However, as the theory of reflexive law became more integrated with autopoietic legal theory (Teubner, 1993), the influence of Habermas' theory decreased and Luhmann's systems theory became dominant.

The reflexive law concept emphasizes the limits of legal regulation and suggests a radical rethinking of the role of law as facilitator and enabler of self-regulation in other social systems. It analyzes the regulatory capacities of the legal system, both in relation to the regulation of other systems and in relation to the legal system's capacity to regulate itself. Law is confronted with a regulatory trilemma according to Teubner (1985). First, it encounters ineffectiveness when the regulated system simply does not respond to the regulatory attempt. Second, if law simply imposes its own solution, it risks legalizing the regulated system. Third, if law yields to the imperatives of the regulated object, it risks becoming. Teubner (1988) suggests that by facilitating self-regulation, law can overcome this trilemma.

There have been a number of attempts to use the reflexive law concept to analyze developments in particular areas of law (see Callies et al., 2009, Part III). For example, Collins (1999) sees modern contract law as a form of reflexive regulation. Reflexive environmental law (Orts, 1995) and reflexive labor law (Rogowski and Wilthagen, 1994; Rogowski, 2013) have been suggested as concepts that can provide new insights in developments of legal subdisciplines. There have also been efforts to apply it in criminal justice studies (Nobles and Schiff, 2000) and to combine reflexive law and postmodern legal theory in constitutional law (Ladeur, 1997; see also Thornhill, 2011).

Law in the World Society

An "unavoidable consequence of functional differentiation" (Luhmann, 1982a, p. 132) is that modern society becomes global. By concentrating on one function and excluding other functions, each subsystem gains a capacity to include all function-specific communications, unlimited by territorial boundaries. Society as a whole becomes the world society (Luhmann 1982a). However, the world society encounters new problems. It can no longer integrate its subsystems by common territorial frontiers. A new metacode emerges in the modern, functionally differentiated world society in the form of a binary code of inclusion and exclusion (Luhmann, 2013/2014, Vol. 2, pp. 16-27).

It is this global dimension and its implications with which the reflexive and autopoietic law concept fundamentally challenges traditional legal analyses. Autopoietic legal theory predicts that legal globalization is unavoidable and that a world legal system is emerging. Global law is plural and derives from other sources than international law, for example, international commercial arbitration (on *lex mercatoria* see Teubner, 1997). It develops largely without the support of states and reflects "the expression of deep contradictions between colliding sectors of a global society" (Teubner and Fischer-Lescano, 2004). These 'regime-collisions' result from the specific nature of the functionally differentiated world society in which an overarching mechanism of coordination is lacking.

Since function systems develop internal structures and regulate themselves in accordance with their autopoietic needs, global law has to become reflexive and consider itself as facilitator rather than authoritative regulator of function systems. Self-regulation of function systems in the world society can be been seen as societal constitutionalization (Teubner, 2004, 2010, 2011), which requires from global law 'double reflexivity' (Teubner, 2012, Ch. 4). Global law has to realize that constitutions are not just second-order legal norms but generate fundamental structures in other social systems with which the world legal system is structurally coupled (*see* Globalization: Legal Aspects).

Abstract

This article examines the emergence of bioethics as a legal discourse and the relationship between technology and bioethics. As a field of study, bioethics functions as a tool to analyze the multifaceted conundrums presented by modern medicine and a way by which those problems can be addressed. This article provides an overview of this broad field of study, beginning with the development of the Nuremberg Code, Declaration of Helsinki, and Belmont Report, and addressing the pivotal medical cases that ultimately spur legislative action, the drafting of codes of professional ethics, and the shaping of legal discourse. The article offers insights on several twentieth-century cases that inspired the development of bioethics in the United States and beyond and has since influenced the development of bioethics and technology throughout the world.

Introduction

According to Warren Thomas Reich, the term 'bioethics' emerged in 1971 – coined by Van Rensselaer Potter, one of the first scholars to advocate establishing a discipline of bioethics (Reich, 1994: p. 320). Potter explained bioethics as "a new discipline that would combine human value considerations with science in general and especially with the 'realities' of biological science in the Man/Earth relationship" (Potter, 1971: p. 1088). A few years later, Potter also endorsed a similar definition put forth by Dr. LeRoy Walters, Director of the Kennedy Institute Center for Bioethics (Potter, 1975). Walters described bioethics as "the study of social and ethical questions motivated by developments in the fields of biology and medicine, and includes subject matter drawn from the natural and social sciences and the humanities" (Potter, 1975: p. 2299). However, the professional standards and ethics framework known today as 'bioethics' began shortly after World War II in a movement to 'humanize' medical education and practice, largely in response to the atrocities carried out by Nazis on Holocaust victims (Pellegrino, 1999: p. 75; Annas, 2009).

Bioethics reflects the convergence of several discourses: law, theology, medical ethics, and philosophy, into a general framework that attempts to answer complex questions that frequently place the individual, medical providers, society, and the state in ethical conflict. Those who frame the field – bioethicists – identify thorny medical dilemmas and attempt to provide clear, normative recommendations to address the challenges of contemporary medical research and delivery. By extension, bioethicists attempt to answer unsettled ethical and moral dilemmas trapped within the intersections of law, medicine, and technology.

The dominant moral dilemmas that frame traditional bioethical concerns address medical experimentation on vulnerable subjects, physicians assisting their patients in suicide or euthanasia, scarce resource allocation and medical futility, human trials to develop drugs, organ and tissue donation, cloning, xenotransplantation, abortion, human enhancement, mandatory vaccination, and much more. The term 'bioethics' provides a lens, language, and guideposts to the study of medical ethics. It is worth noting, however, that medical experimentation is neither new nor exclusive to one country.

Cleopatra, for example, is alleged to have facilitated medical research on her handmaids by authorizing their impregnated wombs cut open for medical experimentation (Bolton, 1881: p. 4354). In 1796, Edward Jenner, an English physician, injected cowpox into James Phipps, a healthy 8-year-old boy (Reidel, 2005: p. 24). In the 1840s, an American gynecologist, Dr. Marion Sims, who is hailed as the 'father of gynecology,' conducted vaginal experiments on slave women without the aid of anesthesia (Kuhn McGregor, 1998: p. 44). In 1900, Walter Reed injected nearly 24 immigrant workers in Cuba with the agent for yellow fever (Cefrey, 2002: p. 29). In the late 1920s, several children in Lubeck, Germany, died from accidental exposure to a lethal tuberculosis vaccine (Coberly and Comstock, 2006: p. 76). In that same decade, Japanese military officials experimented with germ warfare, killing thousands. During the early twentieth century, governments often justified brutal experiments as necessary to protect national security or promote the public health (Harris, 2003). These two rationales remain potent.

Increasingly, economic concerns are included under the broader umbrella of bioethics. For example, should markets serve as an answer to the perceived organ shortage? Should governments rein in the modern-day outsourcing of gestational surrogacy? Bioethics finds its relevance in the persistent absence of formal law on contemporary ethical research problems. Some scholars claim that biotechnology doggedly outpaces law, stretching its reach far beyond the slow, lagging legislative process, which they argue forestalls rather than enables the development of coherent, rational controls over the direction of biotechnologies. In this context, legal rules result by default and happenstance rather than rational engagement.

Much like law and economics, feminist jurisprudence, and other 'new' areas of law, bioethics is an expanding discipline, gaining traction as an authoritative and even necessary method of evaluating medical–legal conflicts. This article tracks the trajectory of modern bioethics, assessing the rise of bioethics, which can in part be attributed to deeply entrenched formalism in the legal jurisprudence, and its turn toward professionalism in the medical and legal academies. It discusses how international tragedies gave rise to guiding documents and principles that ground contemporary bioethics (*autonomy*, *non-malfeasance*, *beneficence*, and *social justice*) and explains that as

technology forges ahead, law and the manufacture of legal rules often lags far behind. The field of bioethics often serves to fill in the gap, offering philosophical insights grounded in law, philosophy, and values to address health care dilemmas. In recent decades, bioethics has contributed to the intellectual ordering of modern medicine and law.

Early Beginnings: World War II, Nuremberg, and the Modern Bioethics Movement

Perhaps the oldest foundational tenet of bioethics can be traced to Hippocrates, the ancient Greek physician credited with the 'Hippocratic Oath,' a pledge commonly taken by new physicians and other health care providers to protect and hold patients' interests above their own. The core of the pledge reflects the Latin edict *primum non nocere*, 'first do no harm,' a moral injunction embraced by health care providers – even if its origins remain somewhat a mystery (Smith, 2005). To this day, the delivery of medicine presents moral, legal, and ethical challenges uneasily resolved by medicine alone. Among these are the demands for medical and scientific information and the use of human participants in nontherapeutic studies to acquire data. Frequently, mixed incentives dominate contemporary biotechnology and medical research practices, sometimes aligning the interests of patients and researchers and at other times subordinating patients' needs to scientists' priorities, such as patenting discoveries, achieving tenure, fame and wealth, gaining notoriety, and assisting national security through military experimentation.

Internationally, governments have justified nonconsensual medical experiments conducted on children, the mentally ill, prisoners, and soldiers based on national security. The collapse of Nazi Germany, the unearthing of medical experiments carried out against Chinese and Russian prisoners of the Japanese during World War II, and the subsequent trials at Nuremberg, where 'Third Reich' physicians and researchers revealed the mass horrors of their human experimentation and broader brutality in the quest for scientific knowledge mark the beginnings of contemporary bioethics. Documents, including photographs and witness statements uncovered after World War II, reveal grotesque research and experimentation conducted on vulnerable populations in China, Poland, and Germany. At a Chinese outpost, for example, the Imperial Japanese army erected a covert military installation where researchers "expose[d] prisoners to [sub-zero temperatures] to … freeze them and then try various techniques to literally dehydrate them, to see what was the most effective way of dealing with frost bite, so that that could be used in warfare as well, both to protect Japanese troupes as well as to effect the enemy" (Targeted Individuals Europe, 2011). At least 3000 died as a result of Japanese medical experimentation. Japanese officials attempted to justify experiments "to develop weapons of biological warfare, including plague, anthrax, cholera and a dozen other pathogens" based on national security interests (Kristof, 1995). In Germany, the Third Reich conducted similar atrocities against Jews and others. Their murderous experiments resulted in an international trial.

The Nuremberg Doctors' Trial, one of 13 trials at Nuremberg, began in 1946 and concluded 1 year later. The trials were conducted by the International Military Tribunal at Nuremberg and were presided over by judges from the four Allied powers (Annas, 2009). The Trials contributed to the articulation and establishment of well-recognized human rights principles in law and bioethics, namely that voluntary consent is an essential component of any medical experiment; any experiment should avoid subjecting the participants to unnecessary suffering; and research subjects must be at liberty to withdraw from human experimentation at any time (The Nuremberg Code, 1949).

Nuremberg Code

The Doctors' Trial ('Trial') stood apart because only judges from the United States presided over those prosecutions (Annas, 2009). At the Trial, prosecutors accused 23 physicians and scientists of performing "murderous and torturous experiments" in the Nazi concentration camps, such as high-altitude and freezing experiments, which resulted in the planned and expected deaths of research subjects (Annas, 2009: p. 21). Researchers who planned and conducted the experiments justified their research on nationalist-medical grounds, claiming the results could benefit German pilots and the broader, German common good (Annas, 2009). Prosecutors also pointed to more than 350 000 forced sterilizations conducted under the Nazi's eugenics regime. In response, Nazi doctors proclaimed that prosecutors were blinded by hypocrisy and exceptionalism, as the U.S. also engaged in eugenics by permitting the broad-scale sterilization of individuals considered socially or mentally unfit. As proof, Nazi doctors cited Justice Oliver Wendell Holmes' opinion in *Buck v. Bell*, a 1927 U.S. Supreme Court opinion sanctioning compulsory sterilization of the 'feeble-minded' (*Buck v. Bell*, 274 U.S. 200, 205 (1927)). Despite this creative defense, which cast light on U.S. involvement in eugenics, seven of the Nazi doctors were eventually sentenced to death by hanging (Annas, 2009).

From this historical perspective, the Nuremberg Trial ushered in modern bioethics. The field's first code of ethics, *The Principles of Nuremberg* (commonly referenced as the *Nuremberg Code*), emerged directly from this landmark prosecution (The Nuremberg Code, 1949). The Principles of Nuremberg, a ten-point statement governing human experimentation, recognized voluntary consent as a central tenet of human research and emphasized that research ought to benefit the social good and doctors ought to prioritize the avoidance of suffering. The 10 principles continue to serve as a framework for medical ethics:

1. Voluntary consent of the human subject is essential.
2. The experiment should be such as to yield fruitful results for the good of society, unprocurable by other methods or means of study, and not random and unnecessary in nature.
3. The experiment should be so designed and based on the results of animal experimentation and a knowledge of the natural history of the disease or other problem under study, that the anticipated results will justify the performance of the experiment.
4. The experiment should be so conducted as to avoid all unnecessary physical and mental suffering and injury.
5. No experiment should be conducted, where there is an a priori reason to believe that death or disabling injury will

occur; except, perhaps, in those experiments where the experimental physicians also serve as subjects.
6. The degree of risk to be taken should never exceed that determined by the humanitarian importance of the problem to be solved by the experiment.
7. Proper preparations should be made and adequate facilities provided to protect the experimental subject against even remote possibilities of injury, disability, or death.
8. The experiment should be conducted only by scientifically qualified persons. The highest degree of skill and care should be required through all stages of the experiment of those who conduct or engage in the experiment.
9. During the course of the experiment, the human subject should be at liberty to bring the experiment to an end, if he/she has reached the physical or mental state, where continuation of the experiment seemed to him/her to be impossible.
10. During the course of the experiment, the scientist in charge must be prepared to terminate the experiment at any stage, if he/she has probable cause to believe, in the exercise of the good faith, superior skill, and careful judgment required of him/her, that a continuation of the experiment is likely to result in injury, disability, or death to the experimental subject (The Nuremberg Code, 1949).

Subsequent documents, specifically the Declaration of Helsinki and the Belmont Report, further developed the bioethics cannon (as discussed below).

Despite near-global agreement that Nuremberg was the birthplace of modern bioethics, some scholars regard the origins of American bioethics as deeply rooted in a subsequent era, the 1960s, a time of heightened medical paternalism. If American bioethics was a phenomenon of the 1960s, the U.S. model of medical philosophy could be distinguished from that of the rogue terrors of Nazi Germany. Albert R. Jonsen, for example, describes the Nuremberg Code as a "beginning that would become bioethics," but places greater emphasis on later developments, such as the Declaration of Helsinki (Jonsen, 1998: p. 134). Similarly, David J. Rothman (1991: p. 62) argued that the Nuremberg Code 'might have served' as a model for American bioethics, but ultimately emphasizes the 1960s as the beginning of modern American bioethics. According to Rothman, the Nuremberg Code was not fully taken up in the United States because "the events described at Nuremberg were not perceived by researchers or commentators to be directly relevant to the American scene. The violations had been the work of Nazis, not doctors; the guilty parties were Hitler's henchmen, not scientists. … Madness, not medicine, was implicated at Nuremberg" (Rothman, 1991: pp. 62–63). Notwithstanding this account, the Nuremburg Code continues to have tremendous influence in the field of bioethics.

Declaration of Helsinki

In 1964, the World Medical Association issued the Declaration of Helsinki on human research (World Medical Association, 2008). Debates emerged about whether the declaration served as an alternative to the Nuremberg Code – which many physician-researchers considered 'overly rigid' because of its forceful edicts and focus on the health and well-being of research subjects – or as an enhancement to the prior document. In the end, the most salient aspects of the Nuremberg Code and the Declaration of Helsinki are quite similar, as both provide guidance to physicians engaged in human subjects research, emphasizing the need to prioritize the *individual's* health and well-being above all other goals.

A decade later, the gathering strength and relevance of a bioethics framework within the legal and medical academies culminated in The Belmont Report, drafted in 1979 by the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research sponsored by the U.S. Department of Health, Education, and Welfare (DHEW). The Report proposed "to identify the basic ethical principles that should underlie the conduct of biomedical and behavioral research involving human subjects and to develop guidelines which should be followed to assure that such research is conducted in accordance with those principles" (National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research, 1979). Their efforts began in the wake of the discovery of the Tuskegee Syphilis Study.

Concretizing Medical Bioethics and Responding to Biotechnology

Paramount to the continued development and refinement of a bioethics agenda were two issues (1) researchers' disregard of the lofty aims of the Nuremburg and Helsinki declarations; and (2) the perception of law's failure to take seriously or incorporate the field's principles into practice. By the 1970s, the demands for a respected and legally sound bioethics agenda became clear due to global controversies involving human experimentation as well as the rapidly expanding fields of medicine, including organ transplantation, sophisticated pharmaceutical therapies, and improved biotechnologies. More than any other country, however, the U.S. advanced at the forefront of both biotechnologies and experimentation. Between the 1950s and 1970s, American physicians, scientists, and government agencies rapidly expanded medical and biotechnological knowledge through human experimentation. A cursory view of this time period provides a glimpse of the depth and range of unethical and illegal experimentation conducted by researchers.

1950: Dr. Joseph Stokes infects 200 women prisoners with viral hepatitis.
1952–74: Dr. Albert Kligman conducts skin experiments on inmates at Holmesbrook Prison.
1953–57: Uranium is injected into nearly a dozen patients at Massachusetts General Hospital.
1953–1960: Central Intelligence Agency conducts Lysergic acid diethylamide (LSD) experiments on hundreds of subjects.
1950s–70s: U.S. Army studies 2300 Seventh Day Adventist soldiers.
1960s: Pharmaceutical companies test 150 experimental drugs on prisoners in Pennsylvania (Hassner Sharav, n.d.).

It became apparent from medical experiments in developing nations, as well as the Tuskegee Syphilis Study in the U.S. (discussed below) and increased medical rationing of sophisticated technologies, that race, sex, and class served as

moderating forces in the acquisition of biotechnological knowledge and delivery of health care. In 1974, U.S. law governing human research finally came to fruition – in significant response to the infamous syphilis study. The National Research Act, enacted by the 93rd Congress, provided a federal response to human research conducted in the U.S. imposing guidelines for researchers and establishing a bioethics commission to advance further recommendations. The law created the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research (National Commission), mandated voluntary, informed consent from all persons participating in studies funded through the DHEW, and required that all research funded through DHEW be reviewed by institutional review boards (IRBs). The end result was the 'Belmont Report,' which introduced what are now considered foundational bioethics principles: (1) respect for persons, (2) beneficence, and (3) justice (*The Belmont Report*, 1979: pp. 23193–23194). Today, the four main principles of bioethics are (1) Autonomy, (2) Nonmalfeasance, (3) Beneficence, and (4) Justice.

The National Commission served as a blueprint for President William Clinton's subsequent formation and launch of the National Bioethics Advisory Commission in 1995 and President George Bush's President's Council on Bioethics, established in 2001 (Protection of Human Research Subjects and Creation of National Bioethics Advisory Committee, 1995; Creation of the President's Council on Bioethics, 2001).

By the 1990s, European nations responded in three ways as follows: (1) by establishing the International Bioethics Committee in 1993, (2) by creating the 1997 Oviedo Convention on Human Rights and Biomedicine, and (3) by establishing the European Conference of National Ethics Committees (COMETH), which promotes public debate on biotechnologies and health sciences (Council of Europe, n.d.). The overarching goal for COMETH is to research interests against protecting human subjects. In recent years, several major European protocols have been established to address genetic testing for health purposes, cloning, transplantation, and biomedical research.

Cases That Shaped Bioethics

Bioethics is shaped by the previously discussed international documents along with a series of pivotal cases highlighting the tensions between medicine, autonomy, and the physician–patient relationship (Fox and Swazey, 2008: p. 215).

There is no shortage of cases, both in the U.S. and worldwide, that implicate bioethical principles, particularly as researchers pursue patents or develop new and lucrative drugs. Moreover, much of this research – particularly radiation experiments – were performed on powerless, vulnerable groups – African-Americans, mentally disabled children, indigenous populations, and the elderly. The cases discussed below do not serve as an exhaustive list. Rather these substantial medical ethics breaches offer insight into the relevance of bioethics, given that in each instance the research was passionately defended not only by the research teams, but by scientists in the field. These cases have greatly influenced the development of bioethics both in the United States and throughout the world.

Research on Women

Coercive Contraception

During the 1970s, in the wake of women's liberation movements occurring in some parts of the world, biotechnological human experiments involving unapproved contraceptives were taking place in some countries. In Zimbabwe, for example, studies using the drug Depo-Provera for contraceptive purposes attracted the attention of human rights groups (Kaler, 1998). Human rights activists alleged that the drug was used to control the population. They pointed to the fact that the drug was not approved for contraceptive use in the U.S. where it was manufactured, but was being used for that purpose in rural Zimbabwean communities. Reports emerged that the drug was administered to some women without their consent and sometimes without their knowledge (Rebecca Project for Human Rights, 2013; Sambisa, 1996). Nevertheless, in a paper published in the *Journal of Medical Ethics*, Professors Malcolm Potts and John Paxman (1984) wrote that despite the 'circumscribed' history of the drug's testing and distribution among poor women in developing nations, to remove it from the market would undermine the choice of women in developing countries to have broad access to various contraceptive medicines. In the wake of investigations, government officials in Zimbabwe banned the drug's use except for treating kidney and uterine cancer (Kaler, 1998).

Research on the Elderly

Jewish Chronic Disease Hospital Study (1963)

In 1963, research began at New York's Jewish Chronic Disease Hospital to study whether the body's ability to reject cancer cells was due to the cancer itself or to another malady, such as a compromised immune system (Katz, 1972). Previous studies suggested that healthy individuals' bodies could reject cancer cells promptly and researchers believed that 'debilitated patients' would similarly reject cancers, albeit at a substantially slower rate (SUNY Cortland Institutional Review Board, n.d.: pp. 4–5).

The study involved the intentional injection of live, foreign cancer cells into 22 senile patients hospitalized with various chronic conditions (SUNY Cortland Institutional Review Board, n.d.). Despite the establishment of the Nuremberg principles and sharp similarities to Nazi experimentation, the study advanced without review board approval or interventions on behalf of the patients. The research subjects were uninformed and misled as researchers convinced patients they would receive a "harmless substance which might cause a slight discomfort" (Morse, 1967: pp. 376–377). The researchers defended the study, claiming they had good reason to "predict that the cancer cells were going to be rejected" (SUNY Cortland Institutional Review Board, n.d.: p. 6). The Board of Regents of the State University of New York subsequently reviewed the study and investigated its lead researcher. The Board concluded that the doctors failed to submit the research protocols to the hospital's research committee and that the physicians responsible for the patients' clinical care were not consulted. The researchers were

found guilty of fraud and unprofessional conduct (SUNY Cortland Institutional Review Board, n.d.: p. 6).

Research on Children and the Mentally Ill

Willowbrook Hepatitis Study

For decades, children's bodies provided tremendous resources for human research, despite their inability to consent to medical trials. The Willowbrook hepatitis study, which began in the mid-1950s, is one such example. The was led by Dr. Saul Krugman and conducted at the Willowbrook State School in Staten Island, NY, a facility for mentally disabled children. Willowbrook remains "a potent symbol of unethical research," with some referring to it as the 'pediatric Tuskegee' (Robinson and Unruh, 2008: p. 80). As part of the study, children housed at Willowbrook were intentionally injected with hepatitis to determine the effectiveness of gamma globulin injections in protecting against hepatitis. The research was based on the premise that infection with a mild form of a viral agent can induce immunity. Krugman and others involved in the study justified the research, claiming that given the high prevalence of infection in the institution, it was practically inevitable that the children would become infected, regardless of whether they were enrolled in the study. Researchers concluded that results of the study could be extremely beneficial to society and to the institutionalized children. The doctors claimed the research could potentially control the 'endemic situation' at Willowbrook. And in fact, one of the results of the research was a reduction in the incidence of hepatitis among patients and employees by 80–85% (Robinson and Unruh, 2008: p. 82).

In the study's aftermath, the scientific community was divided. Some scholars claimed Krugman was unfairly vilified and that no real harm had materialized because the research subjects were already institutionalized and suffered far greater material harms than hepatitis infection. Walter M. Robinson and Brandon T. Unruh (2008) argued that the children's parents were not unacceptably coerced and that Krugman's research was motivated by the desire to help children. However, one of the study's most outspoken critics, Dr. Henry Beecher, an anesthesiologist at the Massachusetts General Hospital and professor at Harvard Medical School, published a paper in the *New England Journal of Medicine* entitled 'Ethics and Clinical Research,' citing the Willowbrook study as an egregious example where patients were not informed that they were subjects of an experiment (Beecher, 1966).

Pfizer Meningitis Study in Nigeria

In 1996, clinical researchers at Pfizer, Inc. (Pfizer), a large American drug company, learned of a meningitis outbreak in Nigeria's northern Kano State. By the end of this epidemic, there were at least 250 000 recorded cases of meningitis and 25 000 deaths. Pfizer, working alongside volunteer agencies (such as Doctors Without Borders) and Nigerian health officials, used the epidemic as an opportunity to conduct a randomized trial of Pfizer's antibiotic 'Trovan.' Pfizer's stated goal for this trial was to obtain "valuable empirical and clinical data on Trovan … [and to] pioneer[] a breakthrough treatment for the Third World" (Ezeome and Simon, 2010: p. 1). At the time of the trial, Nigeria was run by a military government with "one of the world's worst human rights corruption records," which meant Pfizer faced fewer regulatory hurdles in beginning and carrying out the trials (Stephens, 2000). Pfizer prepared and initiated the study in a mere 6 weeks, in contrast to the process in the U.S., which typically takes a year or more (Stephens, 2000).

Two hundred Nigerian children with meningitis were enrolled in the trial. And although the antibiotic was promising, it was also a 'potential blockbuster' for Pfizer, with Wall Street analysts predicting that Pfizer might earn 1 billion dollars if Trovan were approved for its many potential uses (Stephens, 2000). Throughout the trial, Pfizer did not follow various guidelines governing meningitis experiments, such as conducting a second spinal tap within a few days of beginning treatment. In all, 11 children died and many others continued to suffer meningitis-related symptoms including deafness, blindness, seizures, and loss of mobility. According to a Nigerian doctor, the patients did not understand or know they were in a research trial; "they just knew they were sick" (Stephens, 2000). And although Pfizer claims that local nurses explained the research to the children's families, there are no signed consent forms to prove its claims.

Trovan was eventually approved for sale in the U.S. but it was *not* approved for use in children and European regulators prohibited its sale completely, given discrepancies in the Nigerian test results as well as the drug's numerous side effects, including liver damage and death. Pfizer 'roared' in and out of Nigeria in 'a relative eye blink' – leaving 3 weeks after the study began. In 2011, the parents of four children who died during the trial were each awarded $175,000 (Smith, 2011). More compensation settlements were expected to follow from a $35 million fund created under the settlement between Pfizer and Kano State (McNeil, 2011).

Government-Sponsored Research

U.S. Sponsored Syphilis Studies in Tuskegee and Guatemala

In 1972, the most notorious human experiment conducted in the United States ended after four decades (Washington, 2006). Several hundred poor, African-American men infected with syphilis, a sexually transmitted disease caused by a bacterium and treatable with penicillin, served as the uninformed participants in a deadly 40-year study supervised by the U.S. Public Health Service. The men were told only that they suffered from a condition referred to as *bad blood* and that the state would provide free treatments for the illness, the men unwittingly surrendered to the behest of the researchers, providing doctors and government officials broad access to their flesh (Washington, 2006: p. 162).

The men's bodies became human canvases to be poked, prodded, and punctured with lumbar spinal taps. Indeed, the purpose of the study was neither to keep the men alive nor to find a cure for syphilis, but rather to study the effects of syphilis, particularly at death. For this reason, the participants were not provided penicillin – all were treated with pink pills of no medicinal value. In 1932, when the infamous "Study of Syphilis in the Untreated Negro Male" – euphemistically known as the *Tuskegee Study* – began, no research protocols existed in the United States to define the scope of human participation in medical experimentation (Washington, 2006: p. 157). Neither did federal or state laws guide medical experimentation, because such laws had never been enacted.

Ethical protocols remained at the discretion of doctors and their universities or hospitals. By 1947, penicillin emerged as the gold standard treatment for syphilis. However, researchers withheld this vital information from the infected men and their families. The Public Health Service doctors and a team of medical researchers denied the patients antibiotic treatments, withheld information, and prevented or obstructed their access to nearby treatment programs.

Similarly, in Guatemala from 1946 to 1948, the U.S. government, in collaboration with Guatemalan officials in the health ministries and military, infected prisoners, individuals with low IQs, and soldiers with syphilis and other sexually transmitted diseases. The Guatemalan experiments were conducted on 1500 men and women without informed consent, just like the men at Tuskegee. In Guatemala, however, the research subjects were later treated with antibiotics (Stein, 2010). Ironically, the antibiotic treatments were a test protocol and likely not meant as a proactive health measure.

In 1997, 55 years after the Tuskegee study commenced, President William Clinton issued an apology to the few remaining survivors whose crippling conditions made it remarkable that they somehow survived (Washington, 2006). In 2010, the U.S. issued an apology for its involvement in the Guatemalan syphilis study (Stein, 2010).

Human Plutonium Experiments

Human plutonium injection experiments were carried out during and after the Manhattan Project, which ran from 1942 to 1946 (Moss and Eckhardt, 1995). The experiments sought to develop diagnostic resources to "determine the uptake of plutonium in the body from the amount excreted in the urine and feces," an essential tool for protecting workers producing and fashioning plutonium metals for use in atomic bombs (Moss and Eckhardt, 1995: p. 177). The research subjects were injected with plutonium. Whether the patients injected with plutonium provided consent cannot be answered with certainty because all direct participants are deceased and documents that could shed light on this question are scattered, incomplete, or nonexistent. The evidence that does exist, however, makes it almost certain that patients were uninformed about being injected with plutonium. Indeed, until the end of World War II the word 'plutonium' was undisclosed (Moss and Eckhardt, 1995: pp. 213–214).

Cold War Experiments

From the end of World War II and well into the 1970s, the Cold War provided the impetus for government-funded and -conducted experiments. During that period, the Atomic Energy Commission, the Defense Department, the military services, the CIA, and other governmental entities exploited prisoners, drug addicts, mentally disabled patients, mentally ill patients, college students, and soldiers in experiments "to test the effects of everything from radiation, LSD and nerve gas to intense electric shocks and prolonged 'sensory deprivation'" (Budiansky et al., 1994). Rarely were these research subjects aware of the scale and scope of the research, risks involved, or even that they were part of an experiment. Collectively, these experiments are known as 'Project MKULTRA' (or 'MK-Ultra'). In 1976 and 1977, the United States Senate conducted investigations and held a joint committee hearing on MKULTRA (Project MKULTRA, 1977). According to the hearing report, the project sought to study and develop the covert use of biological and chemical materials for 'behavioral control' (Project MKULTRA, 1977: p. 2).

General Vernon A. Walters, Deputy Director of the CIA, testified in 1975 that the experiments "included covert drug tests on unwitting citizens at all social levels, high and low, native Americans and foreign" (Project MKULTRA, 1977: p. 2). Some of the experiments involved administering LSD to unknowing subjects. Researchers destroyed many of the documents related to these experiments. Nevertheless, the uncovered records "reveal a far more extensive series of experiments than had previously been thought," including involvement of more than 86 universities or institutions (Project MKULTRA, 1977: p. 3). Researchers and government officials involved with the Cold War studies were never prosecuted (Washington, 2006). Among those researchers, some continued to lead distinguished careers.

The United States was not alone, however, in conducting controversial and arguably unethical research experiments. Fearing that the Soviet Union was planning a chemical and biological attack, the British Government sought to study germ dispersion. To do so, scientists from Porton Down, the United Kingdom's government military science park, drove a Land Rover through local towns, spraying Zinc Cadmium Sulfide into the air in an attempt to simulate germ warfare. Although Porton Down's authorities argued that the Zinc Cadmium Sulfide posed no health danger, the residents were nevertheless unknowing and unconsenting research subjects. Porton Down's scientists also performed countless experiments on soldiers, who often agreed to be involved in research "in return for payment and a precious pass for 3 days leave." Many were not informed about the substance or purpose of the research and in 1953, serviceman Ronald Maddison died after taking part in a Sarin nerve gas experiment (British Broadcasting Company).

Prisoner Research

During the latter half of the twentieth century, researchers frequently sought the involvement of prisoners in medical research because the stability of prison life (controlled diet, ready availability of subjects for continued monitoring and follow-up) made incarcerated populations attractive research subjects (Office for Human Research Protections, 1993). However, ethicists and others concerned with the treatment of human research participants increasingly question using prisoners as research subjects, contending that the very fact of incarceration makes it difficult, if not impossible, for prisoners to give voluntary and informed consent. For example, prisoners were subjects in many of the MKULTRA and other government-sponsored experiments during World War II and the post-World War II era. In fact, after World War II, the United States was the only nation in the world continuing to legally use prisoners in clinical trials, with federal, pharmaceutical, and cosmetic companies funding a 30-year 'boom' in research involving prisoners (Washington, 2006). In an effort to address abuse in prison medical research, regulations and some federal agencies now require special considerations or protections for

research involving the incarcerated (Office for Human Research Protections, 1993).

Contemporary Challenges

One distinction in contemporary medical research that provides some distance from past ethical breaches concerns the role and rule of law. The firm establishment and broad acceptance of bioethical principles offers greater clarity at the macro level to universities, hospitals, and industry, as well as at the micro level, imposing rules and regulations on researchers. The establishment of firm research protocols has likely reformed modern medicine to some degree. Yet, despite mandatory research ethics training, the establishment of IRB processes, and increased government oversight throughout the world, challenges remain. And, much like egregious experiments of the past, research subjects most likely to be exploited are vulnerable by status: poor, uneducated, and of color. Pfizer's meningitis studies involving Nigerian children provide an important example.

Indeed, contemporary challenges in bioethics reflect the dynamics of past medical research: conflicts of interests, lack of meaningful enforcement, perverse incentives, and unfettered access to particularly vulnerable subjects. However, one major difference separating the early research experiments on vulnerable subjects from that of today is the use of tort law when codes of ethics are violated.

Legal settlements may also cross borders. For example, litigants in Nigeria sued Pfizer in U.S. court after their case was dismissed in Nigeria. Litigants argued that a fair trial could not be pursued in their homeland and successfully argued that Pfizer could be sued in U.S. courts for illegal conduct abroad (*Abdullahi v. Pfizer, Inc.*, 562 F.3d 163 (2d Cir. 2009)). Ultimately, Pfizer settled the claim (McNeil, 2011).

Conclusion

Contemporary bioethics involve a host of medical–legal concerns that extend beyond the conduct of medical researchers to include issues involving the right to refuse treatment, the constitutional 'right to die,' assisted suicide, and the balance between state interest and that of the individual. Bioethical challenges play out in the tensions between family members (illustrated by the conflicts over authority to remove life-sustaining support), in cases involving forced medical treatment, conflicts between pregnant women and fetuses, and medical futility, such as anencephalic babies kept on expensive, life-sustaining medical therapies. The scope of ethical concerns in medicine will continue to expand as technology advances. Most contemporary bioethical challenges and concerns reflect concerns from generations past, including individual autonomy, dignity, fiduciary obligations, justice, and informed consent. The field, though relatively nascent, has a long and complicated history and makes a distinct contribution among legal discourses.

Law: Change and Evolution

Lawrence M Friedman, Stanford University, Stanford, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article focuses first on macroevolutionary change, looking at theories of long-term legal change involving whole systems, groups of systems, or law in general. Theorists discussed include Marx, Maine, Durkheim, Weber, Schwartz and Miller, Galanter, Selznick, and Watson. The second part is concerned with more general theories of legal change. It discusses the 'autonomy' of the legal system, typologies of legal change, the need to distinguish long-run change from short-run change, the differences made by democratic and totalitarian tendencies in society, and the role played by the legal system in social change.

Legal Evolution

There has been a good deal of speculation on the question whether legal systems 'evolve', that is, whether there is some kind of natural, automatic process or direction in which legal systems move and change over time. We might want to distinguish between macroevolution and microevolution. By macroevolution, I mean a theory that law in general, or whole systems or groups of systems, evolves in patterned ways. Microevolutionary theories would try to account for short-term changes in particular systems. Of course, there might be many gradations in between. Take, for example, the theory that common law doctrines evolve over time toward economic efficiency or cost reduction (Priest, 1977; Clark, 1981); the theory assumes a process, somewhat like Darwinian natural selection, that winnows out wasteful or irrational rules (for a discussion, see Elliott, 1985, pp. 62–71). A theory of this sort blurs the boundary between macro- and microevolution. This article will focus first on macroevolutionary change; then, briefly, it will consider more general theories of legal change.

A (macro) evolutionary theory of law would mean that legal systems grow or develop in a pattern of orderly stages. Legal systems would progress, in other words, from stage 1, then move on to stage 2, then 3, and so on. Few, if any, legal scholars believe that any such progression is inevitable. Practically speaking, historians and legal scholars think of legal evolution in a weaker sense: not all systems will reach the highest stage (whatever that might be), but if they do, they will pass through the same sorts of stages (Friedman, 1975).

The whole concept of evolution is, in a sense, distinctly modern, for the simple reason that traditional societies tended to regard their legal systems as essentially immutable. Law was divine, magical, or the product of natural reason, hence basically timeless and beyond human power. Change, if it occurred, might be (for example) some sort of dramatic and divine intervention. On the other hand, insofar as evolution implies 'progress,' it is as unfashionable an idea in contemporary times as is the idea of progress in general.

Any theory of legal evolution has to posit some source of evolutionary change, that is, some force or factor that impels legal systems to move along given paths. What might that source be? It is hard to generalize, but it seems intuitively right to suggest that changes in society drag legal systems along with them, so that stages of legal development will correspond to stages of social development. Most of the theorists discussed in this article fall into this category. In contrast, some people feel that law is, in essence, independent of society, although it may contain within itself some principle of growth or evolution, which unfolds gradually over time.

Such an idea is at least implicit in legal formalism, of both the common law and civil law varieties; development either occurs automatically or depends on the craftsmanship of judges or jurists; in either event, the law unfolds like the flower from the bud. Among modern authors, Alan Watson perhaps illustrates one version of this view: law, for Watson, is "largely autonomous and not shaped by societal needs"; legal institutions, to be sure, do not exist "without corresponding social institutions," but law itself "evolves from the legal tradition." Law is the "culture of the lawyers and … the lawmakers." (Watson, 2001, pp. 263, 264). Law might just possibly possess no special path; it might be changing in no special direction. A sophisticated – and plausible – version of this idea appears in Hutchinson (2005, p. 16); however, with regard to the common law, Hutchinson does state that its development was basically 'contingent upon social and historical circumstances,' and that 'any understanding of law must be deeply political,' that is, explained in terms of a particular time and a particular culture.

Many classical works in legal sociology and allied fields have at least touched on the subject of legal evolution, and most of them fall squarely within the first type mentioned here (Raiser, 1995, pp. 318–334; Elliott, 1985). Marx expressed an evolutionary theory, after all, in his views of the relationship between ownership of the means of production and the organization of society, and this theory had definite implications for the legal order. Sir Henry Maine, in his important book *Ancient Law* (1861), expressed the view that there was a definite pattern in the way legal systems grew and changed. Ancient law began in a patriarchal stage, in which the family, not the individual, was the unit of legal analysis; moreover, the father had basically the key rights and authority within the family. Birth order, gender, and age determined one's legal rights and duties. Society was based on status. The movement of 'progressive societies,' he stated, has gone in a 'uniform' direction: the individual replaces the

family; voluntary arrangements replace ascriptive ones; and legal systems, to use his famous phrase, evolved 'from Status to Contract.'

Implicit evolutionary theories also appeared in other classical theories of law and society. Durkheim, for example, drew a distinction between primitive and modern societies. In *The Division of Labor in Society*, Durkheim distinguished between 'mechanical' and 'organic' solidarity. In traditional societies (societies of 'mechanical' solidarity), rules and norms were held in common. Violations threatened social cohesion and had to be punished. The law was therefore mostly concerned with punishments. On the other hand, in modern society (characterized by 'organic' solidarity), there is a tremendous amount of complexity and interdependence, and legal rules are mostly civil and 'institutive.' In Durkheim's scheme, as in Maine's, there is strong emphasis on contract: societies as they enter the modern world are characterized more and more by voluntary agreements.

The most subtle, and influential, of the classic writings on legal evolution is Max Weber's (Rheinstein, 1954). Weber was interested in the question 'What makes modern law different from older and traditional systems?' The distinctive quality he saw was what he called rationality – essentially, the process of making and interpreting law on the basis of general principles and rules. Oracles, ordeals, lawmaking by charismatic leaders – these are 'irrational' forms of making or finding law. Modern legal systems in developed countries tend (according to Weber) to replace the irrational with the rational. In particular, modern legal systems are characterized by formal rationality, a 'peculiarly professional, legalistic, and abstract approach to law.' A formally rational system uses logic and deductive reasoning to derive results from rules, concepts, and principles. Irrational systems do not produce predictable results – results that can be controlled by the intellect; citizens therefore cannot rely on these processes. Hence modern law, the law of the modern capitalist state, has a natural preference for Weberian rationality.

Weber falls short of arguing that this progression, from the irrational to the rational, is inevitable or predetermined. His discussion of legal history cannot be summed up in this single formula, since Weber describes, in rich detail, at least four stages of development (Sterling and Moore, 1987). Charismatic legal revelation is succeeded by formally irrational 'kadi' justice – ad hoc decision making based on general social norms. Then comes a stage of substantive rationality; in this stage, a systematic body of rules is imposed on society, but less in terms of juristic reasoning than in terms of religious, ethical, or economic considerations. The stage of formal rationality comes last; in this stage, the jurists create a more or less self-contained, highly logical, and systematic body of law, in which abstract legal concepts are arranged in some definite and principled order. But this is merely a more or less idealized picture of the growth of law in the West. Weber does not claim that this is bound to happen elsewhere, and he never quite argues that the movement he describes is irreversible. In particular, modern law has tended to drift away from formal rationality toward what Weber called substantive rationality – law is made or found in accordance with principles and policies (economic, social, and cultural) that are not strictly legal.

Richard Schwartz and James C. Miller (1964; see Wimberley, 1973) tried to evaluate the concept of evolution on a systematic basis. They drew material from 51 different societies and tried to 'scale' the development of legal institutions. Their scales were in terms of legal institutions: the least advanced societies had no police, lawyers, or forms of mediation. Societies develop mediation first, then some form of policing, and a legal profession last of all. Most of the societies that Schwartz and Miller discussed were preliterate.

In a sense, Weber and Maine (although they wrote long before Schwartz and Miller) pick up where Schwartz and Miller leave off, since their main concern was with advanced societies. Galanter (1966), in an important essay, tried to define what makes a legal system 'modern,' which was, of course, Weber's chief interest as well. He suggests a list of 13 traits, which, in his view, set modern law apart from premodern law. The scheme, then, is implicitly evolutionary. For Galanter, modern law is bureaucratic, professional, rational, and universalistic; it is also 'amendable,' that is, it lacks 'sacred fixity.' Friedman (1994) returns to this theme and lists six traits that, in his view, together make up 'modern legal culture.' Modern law is committed to change, reform, and adaptation; it lacks the conception of timelessness of traditional legal systems. It is pervasive, ubiquitous, and frankly instrumental. At the same time, it does contain strong notions of fundamental rights. Rehbinder (2000) also lists a group of 'tendencies' that characterize contemporary law: a strain toward universalism (this was also one of Galanter's traits), but at the same time specialization, bureaucratization, and an increase in the sheer amount of legal material.

Most of these discussions of legal change focus on 'modernity,' and they are descriptive and explanatory. So, for example, Struck (2011) describes a progression from the 'archaic,' through the 'feudal,' to modern capitalism. But in some work, there is a strong normative strain. Selznick (1969), for example, was concerned, above all, with the evolution of 'legality.' In a later work, Philippe Nonet and Selznick discuss a tendency for laws to evolve toward 'responsiveness' (Nonet and Selznick, 1978). These ideas have influenced the work of Gunther Teubner (1983), who described legal systems as evolving from a kind of dry, rule-bound bureaucratic system to a more 'reflexive' one, in which the law, particularly within administrative systems, would be responsive to the needs and wants of the governed, and which would develop rules and procedures that would be just and adaptive. Teubner, like Nonet and Selznick, adds a distinctively normative flavor to the more descriptive tone of Weber. Teubner's views touched off a lively debate (see Blankenburg, 1984); some of the empirical issues raised in this line of work remain to be definitively examined.

Legal Change

The theory of legal change has to be dealt with rather briefly, not because it is less important than the theory of legal evolution, but precisely because legal change is pervasive, and a broad theory of legal change would be nothing more or less than a general theory of how and why the law develops, in both

the long and the short run. Moreover, practically any study in the field of sociolegal history is in fact a study of legal change and of the dynamics of legal change. (For example, studies of lobbying and interest groups are studies of the dynamics of legal change. So, too, is research on the impact of the industrial revolution, the sexual revolution, and every social factor imaginable.)

Still, constant change is one of the most salient aspects of modern legal systems. At every session, legislatures pass laws to amend or modify existing laws or even to embark on a new direction. The same is true of administrative agencies, city governments, and much of the work of courts: they all represent change. Indeed, the public expects change: candidates and parties, in modern societies, feel obliged to present a program, an agenda – in short, they promise change. (Dictatorships, of course, are under no such obligation.) All legal systems are dynamic; and it is part of the legal culture of today to expect them to *be* dynamic.

All modern legal systems, then, accept change as normal. This was not always the case. Many older legal systems (and preliterate systems) consider law as fundamentally immutable or, in any event, beyond the power of mere mortals. Change occurred nonetheless, but often in disguised form – through resort, for example, to legal fictions.

Theories of legal change – theories about what produces legal change – depend, in the first instance, on the answer to larger questions, very notably the question of the 'autonomy' of the legal system. A legal system, if it was fully autonomous, would operate through its own inner logic or program. It would be independent of the outside society. The opposite system would, on the contrary, faithfully follow, reflect, or mirror changes in the outside society. Needless to say, most scholars are not to be found at either pole of this continuum, but somewhere in between. Most orthodox legal scholars cluster closer to the autonomous end of the continuum; social scientists who study law cluster closer to the other end.

In discussing legal change, there are obviously many factors to be taken into account (for one general discussion, see Ferrari, 1997, Chap. 6). Not every legal system will change in the same way. This is true for both internal and external reasons. Societies undergoing rapid change will naturally process more legal changes than relatively static societies. Legal systems, particularly advanced ones, that legitimate change will contain rules, procedures, and institutions for making and processing change. Modern parliamentary democracies emphasize the formal role of legislatures in changing the law, although administrative agencies also have important rule-making power. Also, the role of courts as change agents is important in many if not most societies. Change also originates in customs, practices, and norms, which then influence the change-making institutions.

A major event (war, plague, or revolution), a major innovation (antibiotics, automobiles, or computers), or a major social change (democratization or sexual permissiveness) will inevitably lead to legal change, sometimes on a massive scale; but the exact form of the change is never precisely predictable. The 'outside' event or situation has its impact in a society that already has structures and cultural facts; those structures and cultures will bend and mediate the influences of the 'outside' forces prismatically. The 'outside' forces make an impact through effecting changes in the general legal culture – that is, in the pattern of demands, expectations, and values that concern the legal system – and legal change comes about because of this change in legal culture; it does not flow immediately and automatically from the 'outside' event or situation. Moreover, once a legal structure, doctrine, or institution is in place, it can exert its own force on the legal culture; it affects legal ideology, and it may come to seem natural or inevitable. The process of legal change, then, is dynamic and interactive, and it forms a never-ending chain of causes and effects.

In theory, one can distinguish four types of legal change, depending on the change's point of origin and final point of impact (Friedman, 1975): (1) some change originates inside the legal system, and also causes whatever impact it might have within that system; (2) some change begins inside the system, but in fact does have an impact on society; (3) some change originates outside the legal system, but affects only the legal system and ends there, with no further impact on society; and (4) some change originates outside the legal system and ultimately has some impact on society, that is, it is more or less effective.

The first two are examples of technical change, and include many projects of 'law reform' or codification, within legal systems – the technocratic work of jurists, which has little or no effect on the way that society actually functions. Codification often falls into this category. But sometimes, wittingly or unwittingly, what begins as purely technical change has unforeseen consequences in the larger society. That is, the technical change simply gives some group in society a convenient 'hook' or formal excuse to advance its goals.

A strong 'outside' force or movement should, in theory, produce an impact both on the law and on the society. But often some other social force, movement, or group fights hard to resist change, and the result is a kind of stalemate: a 'law' is passed, for example, after a bitter struggle between interest groups, but the 'losing' group has enough power to prevent effective enforcement.

The fourth type is, in many ways, the most interesting and pervasive. Some changes are quite revolutionary – for example, the type of wholesale change that took place after the Russian or the Chinese revolutions; or, contrariwise, that took place in Russia after the collapse of the Soviet Union; or the total extinction of the legal system of East Germany (Markovits, 1995). Other changes are small or incremental; they produce only a minor effect on some portion of the population.

The discussion in this article has mostly assumed change in formal, overt aspects of law. But legal systems are complex, and there are many instances where one aspect of the system changes while others remain (on the surface) unchanged. For example, the formal or official law might remain unchanged, but the operating system changes, perhaps quite drastically. One example would be divorce law and practice in the United States in the late nineteenth and early twentieth centuries. The official law of some states (e.g., New York) made divorce difficult and expensive; the law in action was completely different. Collusion and other devices made it possible for citizens of New York to get divorces that in theory they were not entitled to have. What kept this dual system alive? Apparently, it was a political situation that for various reasons

was deadlocked. Strong forces of 'morality' prevented the enactment of reform. The growing demand for divorce led reformers to seek other channels, which they did quite successfully. Legal systems very commonly change in this ragged and complex manner (Friedman, 2004; Grossman and Friedman, 2011).

One should also distinguish between long-run change and short-run change (and various gradations in between). In the long run, legal systems are almost infinitely plastic, and they change to fit the shape of the society in which they are embedded. A feudal system will generate a legal system that deals with institutions of feudal society and reflects its norms and structures; a capitalist, socialist, or tribal society will shift its laws to suit the existing system. But in the very short run, random, accidental, or 'internalist' factors may condition or shape forms of legal change. It is this fact in modern societies that promotes the illusion of legal autonomy – the image of a system with a tough and impermeable outer skin. The legal profession itself has to be reckoned with; this can be a powerful group, with a vested interest in resisting certain kinds of change.

The rate and forms of change also depend on whether the society is relatively open and democratic, or relatively closed and aristocratic or totalitarian. In an open society, 'public opinion' is an important factor in shaping the law. 'Public force' would be a more accurate way of putting the matter. 'Public opinion' as such – whatever it is that polls and surveys measure – does not bring about change, except insofar as it influences legislators or judges, or is translated into public action. Public opinion, in any event, is not simply what a poll suggests, or what the majority of the public thinks and feels. *Salience* is an important factor; it affects whether attitudes are translated into behavior. Moreover, in every society, no matter how 'democratic,' there are vast gaps between high and low, rich and poor, powerful and powerless. A wealthy corporation simply counts for more than, say, an impoverished and uneducated slum dweller. As an axiom of legal change, one can start with the notion that a legal rule, doctrine, practice, or institution will change if the social force exerted against it is greater than the force generated to preserve it.

This is a very abstract, and perhaps not very helpful, formulation. The interesting questions are more specific: in any given situation, what *are* the social forces that are in play, and what lies behind the exertion of social force? Moreover, it can be assumed that at any given time, the actual social force exerted on an issue is much less than the potential social force, since most people and institutions, even the powerful ones, most of the time, pay no attention to most legal issues and problems within a society. For this reason, scandals, incidents, and 'horror stories' are particularly important sources of legal change in open societies: they can arouse the sleeping giant and turn potential force into actual exerted force. Hence, the role of the media – which communicates these scandals, incidents, and 'horror stories' – is a particularly powerful, but insufficiently studied, catalyst for sociolegal change (see, for an excellent example, Haltom and McCann, 2004).

Particularly in common law systems, the role of courts in bringing about social change has been much discussed. To what extent, for example, did *Brown vs. Board of Education* (1954), the school desegregation case, make an actual impact on race relations in the United States? (For one view, see Rosenberg, 2008.) That the courts are an important institution in American society and play some role in bringing about social change cannot be denied; the question is how much. There is a small literature on the impact of judicial decisions, but it is hard to come to general conclusions; no two cases seem alike. Modern courts in many countries have the power of judicial review, which may have increased their potential for nudging society along certain paths. There are some signs of dramatic change in judicial culture in the Western world in general. Crusading judges in Italy led to the collapse of the party system; and an activist Spanish judge issued an order directed against General Augusto Pinochet, the former dictator of Chile, who had been virtually immune from prosecution before.

One factor that influences impact is the way that a legal decision and innovations in general are communicated to the relevant audience. We already considered the role of scandals and incidents, and the media's ability to dispense information in selective ways. One should also distinguish between immediate changes (e.g., on the litigants or on some particular group) and more indirect, long-term consequences. Many legal commands have effects that ripple out into society. Unfortunately, research on all these issues is fairly thin.

Studies of legal change are usually studies within one particular legal system; there are, however, some interesting studies that look at *comparative* legal change. More and more, legal systems are not isolated, since societies are themselves more and more interdependent. In a globalized world, legal systems arguably are converging; since the systems face common problems, they tend to generate common solutions (see Friedman, 2011). Not everyone agrees on this, however, and some scholars have argued that global trends have very different impacts on different societies (see, e.g., Engel and Engel, 2010, on Thailand). This is undoubtedly true, but the general lines of development seem reasonably clear.

This article is a revision of the previous edition article by A.M Polinsky, S. Shavell, volume 12, pp. 8510–8517, © 2001, Elsevier Ltd.

Abstract

This article summarizes the literature on the economics of public enforcement of law. First, it discusses the positive aspects of how criminals behave, both from a theoretical and empirical point of view, also touching on how enforcers behave. Next, it discusses the normative theory of how a public law enforcement should be designed within the dominant welfarist law and economics framework.

Introduction: From Beccaria to Becker

The economic theory of the public enforcement of law – a category that chiefly includes criminal law, though it is broad enough to include any law enforced by public authorities, for instance some regulatory law – has its *modern* genesis in the work of economist and Nobel laureate Gary Becker. But several of Becker's ideas were foreshadowed by earlier writers. "Lest the reader be repelled by the apparent novelty of an 'economic' framework for illegal behavior," Becker wrote in 1968, "let him recall that two important contributors to criminology during the eighteenth and nineteenth centuries, Beccaria and Bentham, explicitly applied an economic calculus."

Cesare Beccaria's *On Crimes and Punishments* (1986 [1764]), while by no means a 'law and economics' document, does show, in incipient form, some prominent ideas that would later be associated with the law and economics approach to public law enforcement. This makes sense, as Beccaria was influenced by late-eighteenth-century utilitarianism, which is the conceptual foundation for modern law and economics. Beccaria wrote that "pleasure and pain are the motives for action among sentient beings" (p. 15) and that "the true measure of crimes" is "the harm done to society" (p. 17). He wrote that deterrence is the proper goal of punishment (p. 23), that the harm of the punishment need only exceed the benefit to the criminal for deterrence to work (p. 46), and that inflicting any harm on the criminal beyond this minimum is undesirable (p. 23). Thus, he advocated that nonviolent crimes should be punished only by fines, provided the offender is able to pay (pp. 39–40). Again on deterrence grounds, he advocated that punishments be prompt (p. 36) and certain (p. 46). He advocated a gradation of penalties according to the severity of the crime, on marginal deterrence grounds (otherwise there would be no disincentive to commit more severe crimes) (p. 16), and in particular advocated lower penalties for attempts (p. 69). In fact, one of the reasons he advocated certainty of punishment was that this would allow punishments to be lower, which would make such a sliding scale more effective, as there are limits both to the endurance of the convicted defendant and to the ability of excessively cruel penalties to imprint themselves on the minds of the population to be deterred (p. 47).

Jeremy Bentham, as a founding father of utilitarianism, had a great deal more to say about punishment. Consider a sampling of his views from *An Introduction to the Principles of Morals and Legislation* (1907 [1789]: pp. 171–177). First, punishment might be "groundless" because "the act [is] not … mischievous upon the whole", for instance where there is consent, where "there is a certainty of an adequate compensation," or where the act produced a benefit that outweighed the harm. Second, punishment might be "inefficacious," as, for instance, where the penalty wasn't established or conveyed to the actor at the time of the act, where the actor is undeterrable (as when the actor is too young, insane, or intoxicated), or where the act was accidental. (Here we see clearly the potential conflict between a retributive view and the deterrence-focused view that dominates law and economics.) Third, punishment might be "unprofitable," as when the benefit of deterrence is outweighed by the pain of the prospective criminal at not being able to commit the act, the actual criminal's fear of being caught, the convicted defendant's pain in being punished, or the "pain of sympathy" caused to others. (Here we see the standard utilitarian view, controversial to nonutilitarians, that all people's happiness should be weighed equally, even the criminal's.) Fourth, punishment might be "needless," as where equivalent deterrence could be achieved through education or moral suasion. (Elsewhere (Bentham, 1830: p. 29), he writes that hanging a person "would be folly or cruelty" if hanging an effigy would produce "the same salutary impression of terror upon the minds of the people.")

For whatever reason, the development of a utilitarian theory of public enforcement of law was not particularly active for over a century after Beccaria and Bentham. And thus the world would have to wait until Becker's seminal 1968 article, *Crime and Punishment: An Economic Approach*, "a resurrection, modernization, and thereby", Becker hoped, "an improvement on these much earlier pioneering studies." Becker's approach is primarily normative, but he first develops a positive theory of how criminals behave – or perhaps one should say "how *people* behave," as a core component of his model is that criminals are fundamentally no different from anyone else. Everyone offends when the net benefits of offending exceed the net benefits of obeying the law. Moreover, everyone's utility is counted equally as part of social welfare, so the optimal approach is to set the particular structure of rewards and penalties (in particular, the level of fines and the probability of detection) to induce that level of offending that maximizes the difference between benefits and harms. Because

we take into account as a 'harm' the cost of apprehension and conviction, some underdeterrence is optimal; and because the social loss inherent in imprisonment is also a sort of social harm, it is optimal to use fines, which are virtually costless from a social point of view (as they are merely a reshuffling from one person's pocket to another's) whenever possible. Moreover, fines should relate to the marginal harm from the act and not to the wealth of the offender. On Becker's view, the optimal criminal law would essentially be a species of publicly enforced tort law. Space constraints prevent a fuller exposition of the ideas in Becker's article, which is worth multiple readings by those who are comfortable with differential calculus.

The remainder of this article discusses advances in the law and economic approach to the public enforcement of law since Becker. For more detailed surveys, the reader is referred to Eide et al. (2006), Polinsky and Shavell (2007), and Levitt and Miles (2007), to which this article is deeply indebted.

Law as an Incentive System: Positive Analysis

The previous section has summarized Becker's views on human behavior; the law and economics literature, by and large, has followed the same basic approach. The economic approach holds that everyone (except, perhaps, those with extremely severe mental disabilities) responds, in some degree, to the incentives created by legal rewards and punishments. Therefore, as a matter of *positive* analysis, the challenge is to empirically determine the magnitude of the behavioral response to different types and levels of punishment and other legal rules. And as a matter of *normative* analysis, optimal social design is a matter of fine-tuning the legal rules with these empirical results in mind.

The Distinctiveness of the Economic Approach

How does the positive side of the economic approach differ, if at all, from competing approaches in vogue among criminologists? Levitt and Miles (2007: pp. 458–462) summarize three different branches of the criminological literature and note similarities and differences with the economic approach.

One branch of the criminological literature focuses on the biological factors contributing to crime (Moffitt et al., 2011), from mental disorders and hormonal imbalances to IQ. The economic perspective does not deny the relevance of these factors: these factors can explain the baseline level of crime that exists in the absence of whatever incentives might be created by the probability and severity of punishment. But economists tend not to focus on the determinants of the baseline, instead placing greater stress on the incentives that affect the individual choice to deviate from the baseline. (The modern trend toward behavioral economics can be seen as an attempt to combine psychology and economics and incorporate cognitive limitations and 'bounded rationality' into the model of individual choice. See McAdams and Ulen, 2009.)

A second branch of the criminological literature "stems from Émile Durkheim's concept of 'anomie,' or an absence of clear norms to direct human behavior" (see, e.g., Merton, 1968). The idea of anomie predicts that people turn to crime when they are unable to realize their aspirations through legal means. This is, broadly speaking, consistent with the economic theory in that people with limited legal opportunities may realize greater utility through crime; but the important factor for the economist is the *relative* utility of following or violating the law. The economist would not predict that someone with limited legal opportunities would turn to crime unless the illegal opportunities were more attractive.

A third branch of the criminological literature 'considers the social processes through which criminality is learned or culturally transmitted' (see, e.g., Sutherland, 1956 [1937]). 'Criminality is thus not the behavior of the physically abnormal, but an activity learned from social interactions with others.' This approach is consistent with the economic model, though the economic model still insists that these factors influence criminality only through the familiar pathway of individual choice between legal and illegal activities. Thus, factors influencing criminality could be that one has learned better criminal techniques from the criminals in one's social network, that one assesses the probability of punishment by observing the frequency of punishment among one's colleagues, or that one feels a lesser social stigma of offending because illegal conduct is so prevalent within one's circle (see, e.g., Sah, 1991; Bar-Gill and Harel, 2001).

The difference between the economic and criminological approaches is thus mainly one of emphasis, but the differences in emphasis are significant enough that the two approaches lead to highly distinct modes of analysis in practice.

Theoretical Refinements

Post-Becker authors have extended the model of criminal behavior. Ehrlich (1973) treated the problem as one of time allocation: each person chooses how much time to allocate between legal activities and illegal activities. Within the time-allocation literature, one can also model leisure as a third potential use of one's time (Heineke, 1978; Wolpin, 1978; Schmidt and Witte, 1984).

Criminals' risk preferences have also been the subject of study. Risk preferences come in three flavors: risk-neutral, risk-averse, and risk-seeking. A risk-neutral person is indifferent between getting $10 and a 10% chance of getting $100. A risk-averse person dislikes risk and therefore strictly prefers the $10, while a risk-seeking person has the opposite attitude and prefers the uncertain outcome.

Becker had already considered the conventional wisdom that certainty of punishment has greater deterrent value than severity of punishment. He rephrased it more quantitatively, stating that an increase in probability of detection, coupled with a proportionately equal decrease in the penalty, has an increased deterrent effect. But if this is so, it must be because the greater certainty of apprehension (keeping the expected value of punishment constant) is unattractive to criminals. In other words, given two probability-and-penalty regimes with the same average punishment, where one is more certain and has lower penalties while the other is riskier and has higher penalties, criminals are more deterred by the more certain regime and would rather be subject to the riskier regime. But this attitude toward risk is exactly what we have just defined as 'risk seeking.'

The time-allocation authors listed above extended Becker's treatment of risk preference. Ehrlich (1973), for instance, considered all three types of risk preference; Heineke (1978) concentrated on risk aversion. The precise form of risk preference is important; in most models, risk-averse people offend less when sanctions rise, while results are ambiguous for risk seekers.

Block and Heineke (1975) relax the assumption that the actor only cares about the monetary consequences of obeying or disobeying the law; in their model, dollars earned by legal or illegal means could have different effects on utility, and so one can imagine people with a 'preference for honesty'.

The more complicated the model, the fewer unambiguous predictions one can get from theory alone (though the finding that the probability of arrest has a deterrent effect seems to be fairly robust across models). Choosing among competing theories thus requires empirical testing.

Empirical Results

When testing these models empirically, several challenges emerge.

Levitt and Miles (2007: pp. 462, 463) summarize three challenges. "First, the available data correspond only roughly to the conceptual model." The behavioral theory is individual – but data are aggregated, incomplete, and potentially manipulated by police agencies.

The second problem is 'the identification of causal relationships.' Suppose the deterrence theory is true, and visible increases in policing have a strongly negative effect on offending. But policing levels are not chosen randomly: they are chosen in response to some felt need that is strong enough to overcome the costs involved. Jurisdictions could adopt heavy policing in response to already-high levels of crime, and those policing levels could reduce crime somewhat but not completely. A cross-sectional analysis would then reveal a *positive* relationship between crime and policing, and a naïve researcher would wrongly reject the deterrence hypothesis. Controlling for the factors that lead to high crime could solve the problem, but the econometrician typically knows less than the people he studies, so omitted variable bias will always be a problem. Could not the problem be alleviated by a time-series analysis, which would show the high crime levels being reduced somewhat by heavy policing? Perhaps, but policing levels can also be adjusted in anticipation of exogenous changes in crime levels, so even time-series analysis risks confusing the cause for the effect. More recent econometric analyses tend to be more sophisticated at teasing out true causal relationships, for instance by taking advantage of exogenous policy shocks, such as court-ordered prisoner releases or election-pandering increases in policing (see generally Angrist and Pischke, 2010).

Third, it is difficult to 'distinguish between incapacitation and deterrence.' (When law and economics scholars talk about 'deterrence,' they usually mean 'general deterrence,' the tendency of a penalty to reduce offending among the population at large; 'specific deterrence,' the tendency of a penalty to reduce offending by a specific punished individual, usually is not discussed, except to the extent that incapacitation is considered a type of specific deterrence.) The effects of deterrence are *ex ante* and work even if the penalty is never applied; indeed, one consequence of *perfect* deterrence would be that the penalty is *never* applied, even though officials are always standing by, willing to apply it if necessary. The effects of incapacitation, on the other hand, are *ex post* and only come into play to the extent that the penalty (generally imprisonment) *is* applied. Crucially, the rational choice model that is the staple of law and economics depends on deterrence playing at least some role, so merely finding a negative relationship between imprisonment and crime (which could be entirely due to incapacitation) is insufficient to confirm law and economics models.

Cognizant of these empirical challenges, law and economics scholars have studied the effects of a number of aspects of public law enforcement.

- Policing levels appear to have a large negative effect on crime rates (Marvell and Moody, 1996; Levitt, 1997; Corman and Mocan, 2000; Di Tella and Schargrodsky, 2004).
- Imprisonment has negative effects on crime rates (Marvell and Moody, 1994; Levitt, 1996); some of these effects are due to deterrence and some due to incapacitation (see, e.g., Kessler and Levitt, 1999; Levitt, 1998). Severe prison conditions also have a deterrent effect (Katz et al., 2003).
- The effect of capital punishment continues to be hotly debated, with some papers finding a deterrent effect (Mocan and Gittings, 2003; Dezhbakhsh et al., 2003; Shepherd, 2004) and others taking a more skeptical approach (Donohue and Wolfers, 2006). The estimated effect seems highly sensitive to the estimation method used.
- The effect of gun laws on crime is also hotly debated (compare Lott and Mustard, 1997; Lott, 2010 with Donohue and Levitt, 2001; Ayres and Donohue, 2003).

Of course, whether strategies like more policing or imprisonment are optimal depends not only on their deterrent effect but also on their cost, so the argument that prison deters criminals is consistent with the argument that imprisonment rates are too high because imprisonment is too costly.

The Behavior of Enforcers

The behavior of law-enforcement officials, whether police, prosecutors, or regulatory agencies, is harder to pin down. The field of public choice is devoted to exploring the motivations of government actors, but with the diversity of organizational forms in government and the multitude of competing incentives, valid generalizations seem elusive. For regulatory agencies, for instance, various scholars have proposed the model of the budget-maximizing bureaucrat (Niskanen, 1971), the slack-maximizing bureaucrat (Wyckoff, 1990), and the risk-avoiding bureaucrat (Peltzman, 1973). These different models seem to have obviously different implications for public enforcement of law – the budget-maximizing bureaucrat might invest in too much enforcement, while the slack-maximizing bureaucrat might invest in too little, and the risk-avoiding bureaucrat might avoid high-risk, high-reward law-enforcement strategies. No doubt each of these models might be correct in a particular area.

That said, here are a few suggestive empirical results about the behavior of police officers and prosecutors.

One current area of debate is whether racial profiling by police officers is due to racial bias or is statistically rational (compare Knowles et al., 2001 with Antonovics and Knight, 2009; Barnes, 2005). Another is the effect of court-imposed criminal procedure rules, such as the exclusionary rule or the required *Miranda* warnings (see Atkins and Rubin, 2003 for the exclusionary rule, and compare Cassell and Fowles, 1998 with Donohue, 1998; Feeney, 2000 for *Miranda*).

Prosecutorial behavior has not been heavily studied by law and economics scholars. One question of interest is what prosecutors maximize. Early on, Landes (1974) hypothesized that prosecutors maximize expected sentence length; more recently, Glaeser et al. (2000) have argued that federal prosecutors maximize a combination of social welfare (which leads them to take on the 'worst' cases from a cost-of-crime perspective) and personal career concerns (which lead them to take on difficult, high-profile cases that increase their visibility and improve their skills).

The public-choice literature has also examined the incentives of various government actors, for instance public corrections officer unions or private prison firms, to lobby for stricter criminal law; see Volokh (2008) for one view of the subject.

The Design of Public Enforcement: Normative Analysis

Welfarism: The Dominant Normative Framework

The dominant normative paradigm in law and economics is a form of welfarism. The only facts about the world that are held to matter are individual utilities, though individual utilities may be aggregated in any number of different ways. Different forms of aggregation may give greater or lesser scope to distributive justice considerations, but nothing apart from welfare, such as fairness or justice, should have an independent effect on policymaking (Kaplow and Shavell, 2002; see Volokh, 2011b for one dissenting position).

How should individual welfare be considered? The least controversial position within law and economics is the 'Pareto principle': any policy that improves *everyone's* utilities over the status quo (a so-called Pareto improvement) should be adopted. (Moreover, the dominant position in economics is radically subjectivist, in that the affected person is the only judge of his own utility; a policy improves someone's utility if and only if he would choose a world with the policy over a world without it.) Such policies are of course hard to come by, though if a policy creates winners and losers, one can make such a policy Pareto-improving by transferring some of the gains to the losers, provided that, roughly speaking, 'the winners gain more than the losers lose.'

But what about policies where (as is usual) there is no Pareto improvement because the necessary transfers are not made? The dominant view in law and economics holds that such a policy should still go forward as long as 'the winners gain more than the losers lose.' This concept can be formalized in one of two ways. One formulation urges the adoption of any policy under which, if the policy were adopted, the winners would gain enough to be able to compensate the losers (a so-called 'Kaldor improvement' Kaldor, 1939), though, of course, the hypothetical compensation need never be paid. A related formulation looks to whether the losers would be able to compensate the winners so as to convince them to *not* adopt the policy. If they could convince the winners not to go forward, the policy should not be adopted (again, the hypothetical compensation need never be paid); otherwise, the policy is a 'Hicks improvement' (Hicks, 1939) and should go forward. The Kaldor and Hicks formulations thus differ, though they are identical when the policies do nothing more than change people's monetary wealth.

Simple Models of Law Enforcement

With this theoretical normative apparatus in hand, and taking as given the positive Becker-based model where people offend when the net benefits from offending exceed the net benefits from obeying the law, we may start with a simple model of law enforcement, derive normative results, and gradually work our way toward more complicated models.

No Deterrence of Desirable Acts

First, suppose an act causes some harm but also brings some benefit to its perpetrator. Then, the act should be committed if and only if the benefit exceeds the harm. Thus, hypothetically, if the act is detected with a 100% probability, the fine should not exceed the level of harm. For instance, suppose an act causing \$100 worth of harm were penalized by a fine of \$105. This fine would be too high, because it would wrongly deter the act even if it produced benefits of \$104 and thus added \$4 to social welfare.

Strict versus Fault-Based Approaches

Next, consider the choice between two models of law enforcement: the 'strict' model, under which *any* harmful act is penalized regardless of the benefits it produces, and the 'fault-based' model, under which such acts are penalized only if they reduce social welfare, i.e., only if their benefits do not exceed their harms. In the strict model, the \$100 fine is always imposed, even if the act produced a \$200 benefit and was therefore desirable; in the fault-based model, the \$100 fine is imposed only if the benefit to the actor is less than \$100. Either of these methods produces the same result – acts are deterred if the benefit is less than \$100 and not otherwise. (The strict and fault-based methods, as shown below, are no longer equivalent when incarceration is a possible penalty.)

Probabilistic Detection

Now, suppose the act might sometimes evade detection; for instance, midnight dumping of toxic chemicals might only be detected with a 10% chance. If this is the case, supposing again that the harm is \$100, a \$100 fine will be inadequate to adequately deter the activity. A \$1000 fine, on the other hand, yields a \$100 average penalty (10% of \$1000), so a \$1000 fine will be optimal if people are risk-neutral. At least when money is at issue, the usual assumption is that people are risk-averse, so this sort of \$100 average penalty has greater deterrent value than a \$100 certain penalty. With a 10% probability of detection, proper deterrence would then be achieved with a fine somewhat less than \$1000, say, for instance, \$800.

The Optimality of Maximal Fines?

So far, the probability of detection has been taken as given (first as 100%, then as 10%), and the only question has been the

level of the fine. In reality, though, the probability of detection can be set by policy: greater investments in police, monitors, inspectors, and the like can improve the probability of detection. So how should society jointly set the probability of detection and the level of the fine?

For simplicity, consider the case of risk-neutral actors. A $1000 fine imposed with a 10% probability is just as effective as a $100 fine imposed for certain. (Recall that this contradicts the principle that certainty of detection has a greater effect than the size of the penalty, holding the expected penalty constant. This principle does not hold true for risk-neutral actors, who only care about expected penalties, not about probabilities and penalties as such.) Though both probability-and-penalty regimes have equal deterrent value, the first option is actually strictly better from a social point of view, because maintaining a 10% probability of detection is cheaper, requiring much less investment in law enforcement. By the same logic, a $10 000 fine imposed with a 1% probability is still better, and a $100 000 fine imposed with a 0.1% probability is better yet. One can set the fine as high as the individual's wealth, say $1 000 000, bring the probability of detection down to 0.01%, and the average will still be equal to the amount of harm, $100 (Becker, 1968).

The Optimality of Underdeterrence when Detection Is Probabilistic

In fact, we can do even better. Suppose we reduced the probability of detection even a bit further, say, to .0099%. The average will be $99, so there will be some underdeterrence, as risk-neutral actors commit crimes where the harm is $100 for a private benefit of only $99.50. But these marginal crimes are ones where the harm to the victim is approximately equal to the gain for the actor, so the social loss is approximately zero. On the other hand, any reduction of the probability, such as from .01 to .0099%, results in a nontrivial reduction in the costs of policing, which is a social gain. Thus, some amount of underdeterrence is usually optimal (Polinsky and Shavell, 1984).

Risk-Aversion

Risk-averse actors are even more convenient for society, because the prospect of losing *their entire wealth*, even with a .01% probability, deters them more than $100. To maintain the same deterrent force, the fine can be kept at its maximal level, and the probability dropped further still, with even greater savings for society. However, optimal fines are not necessarily maximal in the risk-averse case. The very convenience of the risk-averse – that they can be deterred with a lower level of fines – is also what makes maximal fines troublesome from a welfarist perspective. Maximal fines with low probabilities impose substantial risk on criminals who have not yet been caught, which is costly for those who are risk-averse. Reducing the fine from its maximal level could, it is true, reduce deterrence (or call for increased police expenditures if the probability of detection were raised to compensate), but on the other hand it would have the advantage of reducing the psychic cost borne by risk-averse criminals fearing the loss of their entire wealth (Polinsky and Shavell, 1979).

The Normative Framework Revisited

One might quibble with this normative framework. Most obviously, the model counts the benefit of the crime to the criminal equally with the harm of the crime to the victim (Bentham, 1907 [1789]; Becker, 1968); moreover, the model counts the criminal's fear of an uncertain punishment as a negative, and as a reason to reduce punishments from the level that would otherwise be optimal. (And this is even before we have introduced the possibility of judicial error: these thought experiments have assumed an errorless enforcement system.) Stigler (1970) and Lewin and Trumbull (1990) have argued that the criminal's gain is illicit and should not be considered as part of social welfare. (Cooter and Ulen (2008) are neutral in this debate.)

But counting the criminal's gain seems to follow from the inexorable logic of welfarism. Consider a status quo world A, and an alternative world B. Each person's utility is slightly higher in B than in A; that is, each person, if asked to choose, would choose B over A. However, suppose that some (perhaps all?) of people's utility in B is due to ill-gotten gains. A social planner, taking the 'ethical path' and refusing to consider the ill-gotten gains, might only compare 'legitimate' utility; he might determine that some (all?) people's 'legitimate' utility in B is lower than in A; and on that basis, he might conclude that B is socially inferior to A. But, as each person (other than the planner) prefers B over A, choosing A over B would contradict the Pareto principle, which is a foundational principle of welfare economics. (This is the sort of argument made in Kaplow and Shavell (2002).)

Extending the Simple Model of Law Enforcement

Marginal Deterrence

The preceding analysis stresses the optimality of maximal fines; nonmaximal fines were only optimal for risk-averse actors, and that result derived from the utilitarian's solicitude for the utility of the criminal himself, who suffers inordinately when, having committed a crime, he fears losing his entire wealth. Another reason for having nonmaximal fines is the need for marginal deterrence. If fines are equal for all offenses, there is no disincentive to commit a more serious offense. Someone who commits a crime might as well compound the crime by shooting the witnesses, if doing so would reduce his probability of being caught. The need to deter these gradations of crime suggests that fines should not necessarily be maximal for less serious crimes, even if criminals are risk-neutral.

Penalties Other than Fines

One straightforward extension of the simple model would allow a choice between fines and imprisonment. Fines are assumed to be cheap: ideally, the convicted criminal simply writes a check. While it is true that fine collection can be somewhat costly, any such costs pale in comparison with the immense social cost of imprisonment, which includes the direct costs of running a prison system, the productivity costs of removing the offender from society (offset by possible incapacitation benefits, see below), and the possibly *dehabilitative* effects of prison, including the brutalization of the inmate, the deterioration of his social capital and the contraction of his postrelease legal opportunities, and the improvement of his criminal knowledge and contacts. Therefore, fines should be used first (ideally, up to the level of the criminal's wealth), and incarceration should only be used as a last resort. Empirically,

one actually observes some tendency to assess more fines on wealthy defendants and sentence them to shorter terms (see Waldfogel, 1995; Meade and Waldfogel, 1998), though perhaps the reason for this is not a desire to save on incarceration resources.

Moreover, when incarceration is a possibility, the 'strict' and 'fault-based' models discussed earlier are no longer equivalent, even though they have identical deterrence properties. Under the strict model, a harm-causing act is always penalized, regardless of whether the benefit exceeds harm; as a result, many desirable acts are punished. Under the fault-based model, a harm-causing act is not penalized unless the harm outweighs the benefit; ideally, if all undesirable acts are deterred, the only observed harm-causing acts are those for which the benefit exceeds the harm, so punishment is *never* actually imposed. When punishments are very costly, the fault-based model should be strongly preferred to the strict model, provided the obstacles to the implementation of the fault-based model (i.e., determining the benefit of the act to the perpetrator) are not prohibitive (Shavell, 1987b).

Goals Other than Deterrence

So far, the goal of law enforcement has generally been assumed to be deterrence (Beccaria, 1986 [1764]), but a full analysis should also consider other goals, several of which may sometimes be consistent with the welfarist framework.

The welfarist framework excludes retributivism as a goal in itself; whether a criminal 'deserves' a particular punishment is normatively irrelevant. Some people in society may have a subjective preference for retributivism (whether it's the victims' desire for vengeance or anyone else's abstract preference for people getting their just deserts), and satisfying this preference is an independent reason for implementing the punishments that retributivism would call for. Retributivist-looking punishments may thus be justified on utilitarian grounds, though the true basis for the punishment would not really be retributivism. (Kaplow and Shavell, 2002 call this a 'taste for justice.')

The welfarist framework is capable of handling incapacitation. As an initial matter, if all undesirable crimes (those where the benefit is less than the harm) are deterred, incapacitation is undesirable: any rational criminal who commits crimes under such a regime is committing desirable crimes, so his continued offending is optimal. Irrational criminals, including but not limited to the insane, may be insufficiently sensitive to deterrent incentives, so incapacitation may be optimal for them. There may be some tradeoff between incapacitation, which counsels releasing anyone whose harmfulness is less than the cost of his incarceration (such as the old), and deterrence, which may require draconian penalties to prevent the commission of the crimes themselves (Shavell, 1987a).

Rehabilitation may also be consistent with a welfarist framework, to the extent that it teaches self-control (i.e., makes criminals better able to respond to deterrent incentives), imparts job skills that will increase the returns to law-abiding behavior after release, or changes criminals' preferences in prosocial ways. As with incapacitation, there may be a similar tradeoff between rehabilitation, which may require non-brutal prison conditions (Chen and Shapiro, 2007), and deterrence, which may require draconian prison conditions (Katz et al., 2003; Bedard and Helland, 2004). Moreover, the effectiveness of existing programs is not guaranteed (see Volokh, 2011a; Donohue and Siegelman, 1998).

For both incapacitation and rehabilitation, any result should be understood as a special case of the general idea that, under a welfarist framework, it can theoretically be optimal to incapacitate or rehabilitate even those who have not (yet) offended, provided such people can be identified reliably enough. Moreover, any intervention to alter people's actions or preferences, e.g., to avoid discriminating or to conserve environmental resources or to enjoy cheaper food, may be optimal under a welfarist framework, whether or not criminal activity is involved.

Judicial Errors

So far, though the detection system has been described as possibly probabilistic, the judicial system has been assumed to be error-free. Errors are not difficult to incorporate into this framework. If an innocent person is 10% likely to be wrongly convicted (Type I error), the rewards for obeying the law decrease, which makes criminal behavior more likely. If a guilty person is 10% likely to be wrongly acquitted (Type II error), the rewards for violating the law increase, which again makes criminal behavior more likely. Thus, *both* kinds of errors dilute deterrence.

For instance, consider an act that causes \$1000 of harm and \$900 of private benefit (relative to a \$0 baseline if the act is not committed). Without judicial errors, and with a 100% probability of detection and a \$1000 fine, a rational person does not violate the law: the payoff for breaking the law is −\$100 (=\$900 − \$1000), relative to a \$0 payoff for obeying the law. With Type I error, the innocent person is 10% likely to have to pay \$1000, so the payoff to obeying the law falls from \$0 to −\$100: a rational person is now indifferent between legal and illegal behavior. With Type II error, the guilty person is 10% likely to avoid paying \$1000, so the payoff to breaking the law rises from −\$100 to \$0: a rational person now strictly prefers to commit the act. Each type of error reduces the difference between the rewards of lawful and unlawful activity (Png, 1986).

Perhaps surprisingly, the possibility of error does not *necessarily* cut in favor of milder punishments, as it might in a more justice-oriented account. Rather, the combined probability of error (20% in this case) acts the same as a reduced probability of detection (as though acts were 20% less likely to be detected). As discussed earlier, the optimal response to such a reduced probability is to *increase* fines (by scaling them up by approximately 20%), at least where actors are risk-neutral. If actors are risk-averse, then, as before, high penalties have the disadvantage that those who may be subject to the penalty suffer by having to bear a high risk of punishment. In the presence of error, this population is much higher than it would otherwise be, as even the law-abiding may accidentally be penalized. Therefore, lower punishments may be optimal in the presence of judicial error when actors are risk-averse (Block and Sidak, 1980).

Conclusion

From Beccaria and Bentham to Becker and beyond, scholars using the economic method have woven a complex theory of

public enforcement of law. Empirical scholars have verified that policing and imprisonment have deterrent effects on crime, though theorists have also warned that the costs of the system are relevant and thus that expensive sanctions like imprisonment should be used sparingly. The use of imprisonment is one area where a more thoroughgoing use of economics could radically change a nation's penal practices in a less punitive direction.

Law Firms

Abstract

Large law firms patterned on the Anglo-American model can now be found in most major commercial centers around the world. Yet, at the very time that mode of the production of law is spreading around the world, the traditional 'Cravath System' upon which the Anglo-American model is based is increasingly under pressure, both by sophisticated clients demanding 'more for less,' and by a range of alternative providers offering competing services at the intersection of law, technology, project management, and other professional expertise. This article seeks to explain this paradox and posits some alternative futures for large law firms in the new 'global age of more for less.'

The majority of lawyers around the world continue to practice alone or in very small and relatively informal groupings (Abel and Lewis, 1988–1995). Nevertheless, there is now a strong trend toward the creation of clearly defined and bureaucratically organized law firms of increasing size and scope. This trend toward large law firms began in the United States during the first decades of the twentieth century (Henderson, 2011). By the close of that century, this 'American mode of the production of law' had spread to the United Kingdom and Western Europe (Trubek et al., 1994). In the first decades of the new millennium, law firms patterned on the Anglo-American Model – as well as a number of Anglo-American law firms – can now be found in virtually all of the important commercial centers in Asia, Latin America, Africa, and the states of the former Soviet Union (Liu, 2008; Flood, 2013; Krishnan, 2007; Wilkins, 2010). Indeed, even some 'plaintiffs'' lawyers – the lawyers who represent individuals in civil cases – are now forming law firms of increasing size and sophistication, particularly in Australia and the United Kingdom (Morrison and Grech, 2009).

Yet, at the very time that the Anglo-American model of the large law firm appears to be spreading around the world, these same institutions find themselves under increasing pressure in their home markets, particularly after the global financial crisis (GFC) that began in the United States in 2008 and eventually spread to slow growth in most of the world's major economies (Henderson, 2014). As a result, large law firms in the second decade of the twenty-first century stand at a paradoxical intersection in which this organizational form is both increasingly ubiquitous, and increasingly viewed as ubiquitously under threat.

This article attempts to unravel this paradox by first charting why large law firms have become the dominant form for organizing legal practice in a growing number of jurisdictions, and then analyzing the forces that are now putting pressure on key elements of the traditional law firm model. The article concludes by positing some alternative futures for the large law firm.

The Rise and Transformation of the Cravath Model

The New York law firm of Cravath Swaine & Moore is frequently credited with pioneering the model for the large law firm in the first decades of the twentieth century (Galanter and Palay, 1991; Swaine, 1946). Four features of the 'Cravath Model' distinguished this firm and its progeny from its nineteenth century American predecessors (Swaine, 1946). First, the *work* of Cravath Model firms consisted of providing a full range of services to corporate clients, as opposed to individuals, with a particular emphasis on transactional and commercial matters, as opposed to courtroom litigation. Second, the *lawyers* in these firms were hired directly out of the country's newly emerging law schools. Once at the firm, they were expected to stay for 6–10 years receiving training from senior lawyers on how to do the work of the firm's corporate clients. Third, at the conclusion of this probationary period, the best of these lawyers were *promoted to partnership* in an up-or-out system in which those not promoted were asked to leave the firm – and, in all likelihood, the large law firm sector altogether, since Cravath Model firms hired virtually no lateral partners or associates. Fourth, Cravath Model firms were *governed* as true partnerships, in which all partners shared equally in the firm's profits and losses (through a 'lockstep' compensation system), and were entitled to equal participation in firm decision-making.

The Cravath Model proved to be particularly well aligned to the market conditions of the developing corporate legal sector in the United States during the first half of the twentieth century. That market was characterized by a rapidly expanding economy, particularly after World War II, and a growing pool of law school graduates as legal education spread throughout the country (Galanter and Palay, 1991). Moreover, during this period very few U.S. companies had sophisticated in-house legal counsel, leading to significant information asymmetry between even the largest corporations and their law firm providers (Gilson, 1990). As a result, corporate clients established long-term and near-exclusive relationships with their principal outside law firms, which in turn provided these organizations with significant freedom to maintain the internal training, promotion, and governance practices of the Cravath Model. Regulatory restrictions and informal norms that prevented or discouraged market behavior, such as advertising or recruiting lawyers away from other firms, further reinforced a protected environment in which Cravath Model firms faced little competition in their home markets for either clients or talent (Galanter and Palay, 1991). By the

'golden age' of the large law firm in the 1960s, law firms organized on the Cravath Model had clearly become the industry standard in the United States, representing the most important clients, hiring the best law school graduates, and occupying the most prestigious and lucrative positions in the American legal market (Galanter and Palay, 1991; Smigel, 1969).

With two notable exceptions discussed below, between 1960 and 2008 demand for corporate legal services in the United States continued to grow at an exponential rate. This growth, in turn, produced an exponential growth in the size, geographic scope, and profitability of large U.S. law firms (Henderson, 2014; Henderson and Bierman, 2009; Galanter and Henderson, 2008). This period of unprecedented growth, however, has been accompanied by significant changes in each of the four core elements of the Cravath Model. First, the *work* of many U.S. law firms has become both broader and more specialized than the work typically performed by golden age law firms. It is broader, in that previously excluded work such as litigation, criminal defense (particularly with respect to white collar and corporate crime), and even plaintiffs work (often for corporate clients who are increasingly willing to file suit) are now an important part of the work of many large law firms (Heinz et al., 2005). At the same time, many law firms have abandoned the full-service model that typified their golden age counterparts and now concentrate on increasingly specialized areas of law. This trend is even more pronounced for partners – and even many associates – who spend virtually their entire careers concentrating on increasingly narrow subsections of transactional practice or litigation (Henderson, 2011).

Moreover, as U.S. law firms have grown in both size and geographic scope, many have abandoned the Cravath Model's traditional *hiring* and *promotion* practices. With respect to hiring, virtually all U.S. law firms now hire associates and even partners 'laterally' from other law firms (and to a lesser extent, government agencies and in-house legal departments), with several firms sourcing the majority of their lawyers in this way (Henderson and Bierman, 2009). Similarly, many U.S. law firms have abandoned their traditional up-or-out promotion policy, creating new categories of professionals such as 'permanent associates' and 'nonequity partners' (Henderson, 2006; Wilkins and Gulati, 1998).

Finally, the *governance* model of the prototypical U.S. law firm has also changed significantly. Although all U.S. firms are still formally organized as partnerships (a model, as discussed below, that is increasingly under pressure in many places around the world, most notably in the UK), few of these institutions retain the egalitarian decision-making structure and lockstep compensation system that formed the heart of the 'partnership model' of golden age large law firms. Instead, with the exception of a handful of top-performing New York law firms (including Cravath itself), most U.S. law firms are organized bureaucratically, with an increasing amount of decision-making authority concentrated in the hands of formal managers – many of whom are not lawyers – and employ an 'eat what you kill' compensation system that rewards partners on the basis of their individual contribution to firm profits (Wilkins, 2007a; Regan, 2004; Chambliss, 2009; Chambliss and Wilkins, 2002).

These modifications to the traditional Cravath Model have in turn affected the way in which large law firms have developed around the world.

Globalization of the Anglo-American Mode of Production of Law

The 'Magic Circle'

The United Kingdom was the first country to develop large law firms comparable to those found in the United States. In the 1940s, the largest English solicitor firms had fewer than a dozen partners. By the second decade of the twenty-first century, four of the UK's so-called 'magic circle' law firms – Freshfields, Linklaters, Allen & Overy, and Clifford Chance – rank among the largest, most profitable, and most globalized law firms in the world, with several other prominent U.K. firms arguably pursuing an even more ambitious global expansion strategy (Flood, 2013).

As U.K. firms grew, many were quick to adopt the major modifications to the Cravath Model that had already transformed U.S. law firms in the 1980s and 1990s. Indeed, by the first decade of the twenty-first century, many of the top English firms were even more specialized, more active in lateral hiring, and more bureaucratic than their U.S. counterparts (Flood, 2013). However unlike most American firms, the majority of large U.K. law firms still retain lockstep compensation as a core element of their structure. This variation in compensation systems has become a key element in the competition between U.S. and U.K. law firms, even as the overall Anglo-American mode of production of law has become increasingly dominant around the world (Flood, 2013).

Globalization of the Anglo-American Model

Spurred by rapid economic growth and the prospect of European integration, large and increasingly sophisticated law firms began to emerge in many Western European countries during the 1980s. These law firms were initially organized as hybrids between the Anglo-American model and the traditional European model, consisting of smaller and more hierarchical firms with strong ties to the academy and the state (Trubek et al., 1994). By the mid-1990s several of these hybrid European firms had grown to more than 100 lawyers, with the largest attempting to compete with the U.S. and the U.K. firms that were rapidly expanding into the European market. This competition, however, proved to be short-lived. Within a decade, many of the top European firms had merged with – or more accurately, been acquired by – Anglo-American firms (primarily from the UK), and those that remain independent have increasingly adopted the core features of the Anglo-American model (Dezalay and Garth, 2013).

A similar transformation has occurred in Japan and the Asian Tigers of Hong Kong, Singapore, Taiwan, and Korea – although regulatory barriers have meant that the Anglo-American model of the large law firm has spread more rapidly in these jurisdictions than has the presence of Anglo-American law firms (Suzuki, 2003). As in Western Europe, in the last decades of the twentieth century a handful of law firms grew rapidly in these jurisdictions to service the needs of

multinational companies investing in these markets, as well as the expanding domestic corporate sector. Like their European counterparts, these Asian large law firms adopted many of the core elements of the Anglo-American model (Suzuki, 2003).

Since 2000, the same pattern has emerged in the BRICS (Brazil, Russia, India, China, and South Africa) and other rising powers. In each of these jurisdictions, one can now find a growing number of large 'corporate' law firms, some of which with hundreds – and in the case of China thousands – of lawyers (Wilkins and Papa, 2013). The best of these law firms now compete aggressively with Anglo-American and European large law firms for both clients and talent in their home jurisdictions. A few have even opened branch offices in major Western commercial centers such as New York and London (Li and Liu, 2012). There continue to be many differences among these new entrants to the large law firm field and their more established Western peers. For example, many emerging market large law firms are still controlled by founding families or partners, whereas most Anglo-American firms transitioned away from family or founder control several decades ago (Wilkins, 2012; Wald, 2009). Notwithstanding these differences, however, most emerging market large law firms continue to use the Anglo-American model as their organizational template.

Theories of Growth

Scholars have offered several theories to explain both the growth and the structure of large law firms. These theories tend to cluster around the traditional poles of supply and demand. The most prominent of the supply-side theories are grounded in the internal dynamics of the original Cravath Model. For example, 'tournament theory' argues that large law firms are growing exponentially because the Cravath Model's traditional 'promotion to partnership tournament' creates an internal growth engine that requires firms to hire multiple associates for every new partner that they promote (Galanter and Palay, 1991). Similarly, 'portfolio theory,' and the related idea of 'reputational bonding' asserts that law firms must grow to diversify their service offerings to protect themselves against fluctuations in demand – e.g., a mergers and acquisition practice to take advantage of increasing transactional activity in a rising economy, and a bankruptcy and litigation practice to attract work when the corporate market is declining or restructuring (Burk and McGowan, 2011; Gilson and Mnookin, 1985). Demand-side theories, by contrast, argue that large law firms have grown as a result of the escalating demand for sophisticated corporate legal services (Thomas et al., 2001; Sander and Williams, 1989).

Both supply and demand theories have made a valuable contribution to our understanding of the growth and development of large law firms, particularly in the United States during the period before 1990. However, recent events in the U.S. legal market, and even more importantly, evidence about the growth and operation of large law firms around the world, underscore the limitations of each of these explanations. Thus, as Anglo-American firms have largely abandoned the Cravath Model's traditional up-or-out hiring and promotion practices, tournament theory has become a far less persuasive explanation for law firm growth, as even that theory's most prominent original exponent concedes (Galanter and Henderson, 2008). Instead, the overwhelming majority of U.S. and U.K. law firms have achieved most or all of their growth in the last two decades through a combination of lateral hiring (of individual lawyers or increasingly teams or whole practice groups), mergers with – or, more often, acquisitions of – other law firms (including an escalating number of international combinations), and the creation of new classes of lawyers who are neither associates nor partners, including contract lawyers, permanent associates, of-counsel lawyers, and nonequity partners (Aronson, 2007). This pattern of growth by lateral hiring, merger and/or acquisition is even more prevalent for law firms in emerging markets such as China (Liu and Wu, unpublished manuscript). Indeed, although firms in these jurisdictions are outwardly structured along the lines of the Cravath Model, it is not at all clear how many of them are running anything like a Cravath-style promotion to partnership tournament in which those who are promoted gain any significant equity or decision-making interest in the firm (Krishnan, 2013; Liu, 2008). Yet these same firms are among the fastest growing law firms in the world.

Nor are contemporary U.S. and U.K. law firms typically organized along the full-service model predicted by portfolio theorists. To the contrary, as indicated above, specialization rather than diversification has been the dominant trend, with many law firms shedding traditional countercyclical or noncyclical practices such as labor and employment law or trusts and estates in favor of concentrating on high-margin work such as mergers and acquisitions, securitization, and high stakes litigation – while other firms have rushed in to fill the void by building law firms that specialize in the areas that have been abandoned by other players.

Demand-side theories also do not adequately explain the current structure and practices of large law firms around the world – at least if demand is thought of as simply an external force independent of the market actions and incentives of law firms themselves. Escalating demand for corporate legal services around the world has clearly played a significant role in fueling the growth of large law firms. Consider, for example, the BRICS. Beginning in the 1990s, each of these jurisdictions liberalized their economies to a greater or lesser extent, pouring significant public and private resources into fostering the development of a vibrant corporate sector in which private, state-owned, and foreign companies were all given a role (Trubek et al., 2013). Predictably, this development generated the need for a host of new laws and legal institutions to manage the interface with the global economy and to regulate the growing domestic corporate sector (Papa and Wilkins, 2012). And just as predictably, this flood of new domestic and global regulation has in turned fueled the growth of a vibrant corporate legal sector capable of understanding, interpreting, and manipulating this new regulatory framework (Papa and Wilkins, 2012).

Nor is it surprising that the law firms that have developed in these jurisdictions to meet this rising demand resemble – at least superficially – the Anglo-American model. As 'economic globalization' has led Western multinationals to locate larger and more sophisticated operations in these jurisdictions, lawyers practicing within the BRICS have every incentive to

signal that they can provide the same level of service as the Anglo-American law firms that have followed their clients to the BRICS to capture this same work. The easiest way to do so is to appear to replicate as nearly as possible the industry standard of the Anglo-American Model (DiMaggio and Powell, 1983). The 'globalization of knowledge' reinforces this institutional isomorphism, as lawyers educated in the West who have received a subtle but powerful indoctrination in the superiority of the Anglo-American model of the large law firm seek to create institutions that at least appear to adhere to its tenets (Papa and Wilkins, 2012). Finally, the 'globalization of governance,' including the proliferation of multinational regulation in areas such as trade, antitrust, and anticorruption, has increased the need for both Western multinationals and the growing number of multinationals based in the emerging economies to obtain access to the kind of sophisticated, integrated, and efficient legal services that have come to be associated with Anglo-American large law firms operating under the Cravath Model (Papa and Wilkins, 2012). Collectively, these three forms of globalization have created a powerful demand for Anglo-American style large law firms (Wilkins and Papa, 2013).

Nevertheless, demand alone cannot explain the patterns of law firm growth around the world today. To begin, although demand in the BRICS and other emerging economies has continued to grow since the GFC, the demand for corporate legal services in the U.S. and other developed legal markets has been flat since 2010 – and significantly down from the historic high in 2007 (Henderson, 2014). And yet, the large law firm sector continues to grow, expanding by 4% in 2013 (Jones, 2014). Virtually all of this growth, however, has been as a result of mergers and acquisition, as law firms try to hold on to their share of demand by acquiring lawyers and law firms with existing client relationships (Jones, 2014). It is already clear that in many cases this strategy is unlikely to be successful. Indeed, some of the most spectacular law firm failures of the last few years have been the result of law firms that attempted to grow their way to increased profitability by rapid and large scale mergers and/or lateral hiring (Barrett, 2013; Lattman, 2012). And yet, there is a persistent sentiment among many law firms that if they do not grow – regardless of overall profitability – they will lose their 'star' partners to law firms that are growing (Henderson, 2014; Aronson, 2007).

Economic globalization is increasingly driving this perception. Much of the growth in the U.S. legal market since 2013, for example, is the result of a wave of international mergers (Jones, 2014). Much of the rest is due to the dramatic expansion in the number and size of foreign offices, particularly in China and other Asian markets (Silver et al., 2009). Yet, there is very little evidence that this foreign expansion has increased profitability (Stern and Li, unpublished manuscript). Even with respect to domestic mergers between law firms based in the US, the evidence is quite mixed about whether these combinations increase profitability (as opposed to gross revenues), particularly relative to the overall U.S. market due to the difficulty of integrating divergent law firm cultures and practices (Aronson, 2007). Similarly, 'star' lawyers who are recruited away from one law firm for the purpose of obtaining their 'book of business' of important client relationships – frequently at the cost of a significant premium – often leave within a few years for other firms that offer even more lucrative guarantees, without ever producing the promised increase in market share or profitability (Coates et al., 2011). Global expansion has arguably fared even worse, as a host of cultural, linguistic, and historical differences between Anglo-American firms and the law firms, lawyers, and clients they seek to serve in emerging markets have multiplied problems of postmerger integration and identifying and retaining 'star' talent. Indeed by many estimates, even in booming legal markets such as China the overwhelming majority of the branch offices of non-Chinese firms are only marginally profitable at best (Stern and Li, unpublished manuscript). A recent study of Chinese law firms suggests that rapid expansion of these firms by merger, acquisition, and foreign expansion may be following a similar course (Liu and Wu, unpublished manuscript). The premise of all of these combinations seems to be that growth will fuel demand rather than the other way around.

Although counterintuitive, a growth – or more accurately lawyer-led – theory of demand is not without precedent. Demand-side theories treat lawyers as passively responding to corporate clients' need for the services lawyers in large law firms provide. American lawyers, however, have always played a more active role in promoting the demand for their services than this model suggests. Thus, the lawyers who encouraged their corporate clients to use litigation as a tool for resolving business disputes are partly responsible for the increased demand for litigators (Galanter and Palay, 1991). Similarly, law firms such as Wachtell, Lipton, Rosen & Katz and Skadden, Arps, Meagher, Slate & Flom helped fuel the mergers and acquisition boom by developing new strategies for hostile takeovers (Caplan, 1993). It is this entrepreneurial style of lawyering that is spreading around the world.

The problem for lawyers in traditional large law firms is that this strategy may have worked too well. Precisely because Anglo-American law firms have been so successful in both responding to and helping to generate corporate demand, mimicking the key forms and practices of these law firms has become a critical form of symbolic capital for aspiring corporate lawyers around the world – regardless of the underlying economics (Liu and Wu, unpublished manuscript). The result is a proliferation of large law firms that look and feel increasingly alike, all with a symbolic imperative to grow, and all chasing a market where the key decision-makers are under increasing pressure to reduce the amount of money that they spend on corporate legal services (Wilkins, 2012). This dynamic, in turn, is putting increasing pressure on the Anglo-American model of the large law firm, ironically most urgently in the country of its birth.

The Death of Big Law?

The GFC had an immediate and dramatic effect on the market for corporate legal services. Demand for the kind of mergers and acquisitions and securitization work that had fueled so much of the growth in the global corporate legal services market declined significantly (Henderson, 2014). Law firms that relied heavily on these transactions were especially hard hit, with several going out of business. Moreover, unlike previous downturns in the legal market in 2001 and 1991, this

decline in transactional work was not counterbalanced by an increase in the demand for litigation, as companies sought out less expensive ways to resolve disputes arising from the GFC (Thomson Reuters, 2012). The net result was that by the end of 2009 many large U.S. law firms laid off significant numbers of associates and support personnel, with several also de-equitizing and/or laying off partners (Henderson, 2014). By 2010, law firms in the UK and Western Europe were following suit. And while the BRICS and other important emerging markets have fared better than the U.S. and other developed economies, growth in these countries has also slowed, as has the foreign investment from the West that was fueling so much of the corporate legal market in these jurisdictions (Li and Liu, 2012). Although economic growth has begun to rebound in the U.S. and most other major economies around the world, the legal market has grown more slowly, with hiring (particularly at the entry level), growth, and profitability all either flat or below prerecession levels (Henderson, 2014).

Both the size and duration of these changes have led some academics and more than a few professionals to conclude that we are now in the midst of a paradigm shift that will result in 'The Death of Big Law' – or even more apocalyptically 'The End of Lawyers' (Scheiber, 2013; Ribstein, 2010; Susskind, 2008). It is still far too early to tell whether anything this dramatic will take place – and most reasonable observers think it is unlikely that large law firms based on the Anglo-American model will soon disappear from the legal scene (Weiss, 2013). After all, projections about the death of the big law firm model have been made since the 1991 recession, and pundits have been predicting the demise of the billable hour for decades (Kronman, 1993). Nevertheless, there are good reasons to believe that a set of fundamental changes that have been accelerated and sharpened by the GFC are likely to have an important effect on the future of the large law firm.

Three such changes are especially important. First, throughout the economy – and increasingly in the market for corporate legal services – there has been a dramatic reduction in information asymmetry between buyers and sellers. This gap began closing when corporations started to hire sophisticated in-house legal departments in the 1980s, a trend that is now spreading around the world (Gilson, 1990; Wilkins, 2012). In recent years, however, in addition to their own knowledge of the legal marketplace these in-house lawyers can now access a significant amount of data about the price and performance of law firms (and the individual lawyers who work in these organizations) from a range of public sources, and, more importantly, a new industry of private consultants dedicated to helping companies reduce their expenditure on outside law firms. As a result, sophisticated general counsel have the ability to take legal work that law firms traditionally sold as an integrated whole – e.g., 'class action litigation,' or 'a $500 million acquisition' – and 'unbundle' it into its component parts – e.g., 'discovery,' 'pretrial motions,' and 'trial,' or 'due diligence,' 'asset pricing,' 'negotiation,' and 'document drafting' – and then spread those different aspects of the work across an increasingly global supply chain of legal producers (Regan and Heenan, 2010; Daly and Silver, 2007).

Second, this trend toward disaggregation has in turn spurred the development of a host of new producers that now aggressively compete for a portion of the work on this increasingly global legal supply chain. Thus, when sourcing 'legal work' general counsels can now choose among legal process outsourcing organizations located in India and other low-cost jurisdictions, electronic discovery companies, contract lawyers, and other temporary staffing solutions, the Big Four accountancy firms which now offer advice on litigation management and deal pricing, and, of course, a growing number of increasingly sophisticated law firms around the world (Rostain and Regan, 2014; Regan and Heenan, 2010). Many of these new competitors are organized as corporations, thus giving them easier access to capital and managerial resources than law firms (Weberstaedt, 2013). As a result, these newcomers are increasingly developing new products and services that further challenge the large law firms' business model (Hadfield, 2014). Traditionally, law firms have relied on a steady increase in the hourly rates that they charge corporate clients, and an equally steady increase in leverage (the percentage of associates, who do not share profits, to partners who do) to drive profitability. But as corporate consumers become more sophisticated about their legal needs, and have greater access to a global network of providers willing and able to provide these services, law firms have had a more difficult time utilizing either of these strategies. Instead, companies are demanding greater transparency and accountability from law firms about how they are doing the company's legal work – and requiring that the law firms price these services by their 'output,' as measured by the value to the company, as opposed to the traditional 'input' model based on the number of associate and partner hours it took to produce the work (Wilkins, 2012).

Finally, this pressure on the law firm's traditional business model is in turn exposing problems in their human capital model. Notwithstanding the current downturn in entry-level hiring, large law firms face increasing pressure to attract and retain the 'best' associates and partners. Demographic changes in the pool of entrants to the profession are making this competition even more intense. Law is increasingly a 'feminized' profession, where the majority – and in many countries, the overwhelming majority – of entrants are females (Michaelson, 2013). Yet the career path in large law firms is not only designed for a man, but a man who has a wife who does not work – a rarity in many societies (Wald, 2010). Indeed, the fact that law firms have had a poor record of integrating lawyers from all nontraditional backgrounds poses an important challenge to these organizations in a world where the talent pool is more diverse in every way – including a new generation of lawyers, many of whom have a different orientation toward work and family than their Baby Boom and Generation X predecessors (Furi-Perry, 2013; Wilkins, 2007b). The steep decline in U.S. law school applications and enrollment since 2010 will only sharpen the challenge that law firms will face in recruiting and retaining top talent in the coming years (Tamanaha, 2012).

Thus, as we approach the midway point of the second decade of the twenty-first century, the profits of Anglo-American model law firms around the world are being squeezed in three directions: vertically by increasingly sophisticated corporate clients demanding 'more for less'; horizontally by competition from other law firms and from a range of new competitors seeking to 'hollow out' the work done by law

firms, either by removing routine work from the bottom through technology and process engineering, or by capturing strategic work at the top by employing multidisciplinary expertise; and internally by a 'war for talent' which, in a human capital-intensive business, talent will inevitably win. How law firms respond to this triple squeeze will determine the future viability of the Anglo-American model of the large law firm.

The Future(s) of Large Law Firms in the Global Age of More for Less

Whether the changes outlined above herald the Death of Big Law, it is quite likely that many big law firms will not survive. Some will fail outright. But many more will be absorbed into larger entities as the pace of law firm mergers and acquisitions continues to accelerate. Moreover, as the recent merger between China's King & Wood and Australia's Mallesons Stephen Jaques and the UK's SJ Berwin underscores, much of this next wave of consolidation in Anglo-American model law firms will be led by firms with their origins outside of either England or the United States. It is unlikely that large law firms will ever reach the level of concentration that we see in other professional services such as accounting or investment banking. Although globalization rewards increasing size and scope, variations in law, language, and culture will continue to place a premium on local know-how – and "know-who" (Dezalay and Garth, 2011). The resulting "globalization" (Silver et al., 2009) will leave room for a range of law firms from globally integrated full-service providers to boutiques and national champions that seek to serve particular geographies, industries, or specialties. Nevertheless, the stratification among these diverse law firm providers is likely to increase, as the number of firms able to command premium pricing for customized 'bespoke' legal work shrinks as corporate clients drive to reduce their demand for this kind of high-end service (Susskind, 2013, 2008). The trend toward removing regulatory barriers that prevent law firms from competing across geographic boundaries – a trend that soon may be mandated by international agreements such as the General Agreement on Trade in Services – is likely to further stratify the relative winners and losers in the global large law firm market (DeStefano, 2012; Terry, 2010). Indeed, deregulation, technology, and the infusion of investor capital are likely to further the development of larger and more sophisticated law firms serving individual consumers as well (Hilborne, 2014). The fact that Jacoby & Meyers, one of the largest law firms in the United States, has filed suit to allow external investment in the American market underscores the dramatic changes that could reshape the law firm market in all sectors in the coming years (Glovin and Jeffrey, 2013).

How much space will ultimately remain for large law firms seeking to occupy the 'bespoke' niche that Cravath Model firms traditionally viewed as their exclusive domain will depend upon both the ability of new providers to produce 'disruptive innovations' that capture a greater share of high-end legal work, and the willingness of law firms to 'disrupt themselves' by absorbing these new innovations into their existing business models (Christensen, 1997). The key to success for both of these efforts will be the development of new and better metrics to measure the *quality* of legal services as well as the *full cost* (long-term as well as short-term, opportunity costs as well as production costs) of producing these outcomes. Advances in artificial intelligence and the use of 'big data' to predict future trends and performance will give both 'disrupters' and large law firm 'incumbents' the opportunity to develop such metrics. Those providers that harness these new tools most effectively and efficiently will determine how much of the nineteenth century Cravath Model that underlies the current Anglo-American mode of the production of law will survive into the middle decades of the twenty-first century.
